THE VETERINARY RECORD

Index: July 1911 to June 1912.

Abdominal complaints W. Tart 220	Anthrax, unusual case in a mare, J. H. Carter 2	Col. John Anderson (obit.) 745
— wound, with protrusion of intestine in a cat E. Wallis Hoare 307	— in the horse, G. Wartnaby 35	Russian service, Extract from statistics 746
About a gamekeeper and a bishop 829	— death from 62	Maj. D. C. Pallin (obit.) 784
Abcesses, cold, of bones, Two cases of 188	— in central markets, London 63	Annual dinner 829
Abcess, Hepatic, opening into posterior vena cava 188	— in horses, C. Wood Page 67	Army horses 655
— Sub-sacral, two cases 186	— in goats, G. Mayall 83	Army horse shoeing 543
— Sub-lumbar 164	— epizootiology of Stewart Stockman 122	Arnoline culture for rats 145
Accidents caused by ingestion of foreign bodies in the pigeon 530	— notes on an outbreak of, E. H. Pratt 255	Ascaris megalocephala, action of the — poisoning 308
Acorn poisoning W. R. Davis 278	— several outbreaks of 484	A useful paper 581
— Deaths from 283	— human, in Germany 582	A Veterinary History 673
— G. Mayall: J. H. Parker 292	Antirabic vaccine 171	A wonderful profession 146
— H. Taylor 323	Anti-rinderpest serum, Peritoneal washings in Maj. F. S. H. Baldrey 55	B. coli as a parasite of plants 240
— 303, 334	— Cultural method of hyper-immunising animals for the production of 490	Bacteriology of leprosy, a new view of the 493
— W. T. Brooks, H. Yeomans, H. L. Pemberton, J. Gold 354	Antistreptococcal serum, Treatment with, E. A. West 597	Balliol College herd 63
Acorns as food for stock 302	Appointment of V.S. by Chelmsford C.C. 784	Barnet fair 168
Actinomycoosis Walter Jowett 298	A practitioner's study 489	Bengal Veterinary College, annual report of the 176
— in Norway 643	A presidential address (Connaught) 545	Bier's treatment by elastic compression 69
— Multiple 643	A "Presidential" in Colorado 184	Bilateral intercommunication of the lymphatic system 502
— of the rectum in the horse 339	A question for Irish veterinary inspectors 629	Bismuth injections into fetulæ 234
— Peritoneal, in the ox 678	ARMY VETERINARY SERVICE—	Board of Agriculture, changes at the 284
Action at Dumfries—ringbone? 312, 344 (See Ringbone)	Gazettes— 15, 67, 145, 172, 184, 200, 216, 228, 259, 275, 303, 335, 384, 400, 414, 440, 456, 486, 499, 527, 544, 563, 579, 596, 611, 639, 672, 687, 729, 746, 784, 800, 815.	— Development Fund 815
— by V.S. at Paignton 414	The Nile Campaign, 1884-85 4	— Grants 815
— of eserine, The 106	Nile Expedition, 1884-5, V.S. E. E. Bennett 6	— Inspectorship and Post-Graduates 816
— on a certificate of soundness 795	— V.S. S. M. Smith 19	Bony tumour of the maxilla J. P. Heyes 770
Address at Camden Town, The 217	Report I.C.V.D. United Prov. 201	Bovine diphtheria, an outbreak of 659
Addresses wanted by Registrar 303	Veterinary work in the Punjab 217	Bovine diseases 261
Adrenalin in purpura hæmorrhagica 5	Report on French operations for relief of Fez 262	Bovine tuberculosis—its intercommunicability A. M. Trotter 504
A horse doctor for asses 143	Report of A.V.D. with Suakim Field Force, 1885 263	Bracken poisoning 167
A judge on doctors J. Nicol 86	Report C.V.D. India, 1910-11 317	Brain symptoms, cases showing E. A. Phipps 143
A living freak 86	Abolition of Inspector General in India 334	Bronchial lithiasis 176
Alleged cruelty—contradictory evidence 784	Report C.V.D. Central Provinces 1910-11 321	Cæcum, impaction of 705
Alleged fraudulent conversion 728	Lt.-Col. Evans, C.I.E. 84, 369	Calcium, Effect of on Bacteria 627
A new ecraseur, G. H. Wooldridge 410	Report (I.C.V.D.) of officer investigating camel diseases, March 1911 477	Camel diseases, report of officer, I.C.V.D., investigating, A. S. Leese 477
A new Veterinary Association 386	Papers set at entrance exam. Jan. 1912 527	Cancer of bladder, with hydro-nephrosis in a dog 789
Amendment Bill and the objectors H. Dyer 36, 68	Papers set at Entrance Examination, 1912 527	Cancer of the liver in a cow, primitive 39
— A. I. McIntosh 36	Army horse-shoeing 543	Cancer, massive pulmonary 385
— and the objectors 51	Transport and horses (Army estimates) 575	Cancer research 312
— The 68	Army horses 659	Canine motor-car accidents, Twelve F. J. Taylor 356
Amendment Act, objectors to the Bill 83	A War Office regulation 739	Canine tuberculosis 441
Amputation of the penis, W. N. Thompson 359		Canker of the horse's foot, an improved method in the treatment of, A. W. Noël Pillers 675
An appeal for our dumb friends 612		— treatment of T. Parker 689
An enquiry into patent medicines 473		— T. Aubrey, A. W. Lawson 698
Aneurism of posterior aorta, H. B. Eve 278		— H. Lomas 732
Annual dinner R.C.V.S. 698		
Annual general meeting, The 769		
Annual Report by the Veterinary Inspector for City of London, 1910, T. Dunlop Young 64		
Anomaly of sexual organs in a horse, S. S. Sokolov 661		

Canker, Ancient and modern treatment of	704	Cruelty to whales 198, Charge at Eastbourne 243, Case at Hull, 259, Charge at Wigton—dismissed 271, Prosecution in Glasgow, D. Campbell 486, 512, To a horse at Llanfair 496. Prosecutions at Reigate—dismissed 525, Charge at Folkestone, mechanical lameness—dismissed 575, Charge at Brentford—imprisonment 576, Charge at Plumstead, mechanical lameness—dismissed 576, Scoring pigs—fined 687, Case at Wolverhampton—dismissed with costs 697, Alleged—contradictory evidence 784	Early X-ray work 369 East Coast Fever, reported method of immunising 131 Echinococcosis and distomatosis in the liver of the pig 475 Effect of calcium on growth of bacteria 627 Election addresses, W. Burt: W. Packman 744 Embryonic filaria causing symptoms of dourine 476 Epilepsy in the horse 691 Epithelioma, Papillary, of the bladder in a pig 136 Epizootic abortion in cattle E. H. Pratt 293 Equine hay fever 565 Erysipelas John Cameron 372 Eserine, on the action of Prof. A. E. Mettam 106 Esperanto for the International Vety. Congress F. E. Place 800 Evidence, The present conflict of in police courts 391 Evidence in police courts, Treatment of J. H. Willett 533 Evidence, Expert, police court 579 Everson of bovine uterus, Chloral in treatment of 153 Experiments on living animals 110 Exportation of horses, The 115 Export of horses 697 — live stock and veterinary duties G. L. Y. Ingram 456 Expulsion of cotyledons in a cow 788
Can R.P.'s use V.S.? 172	"Capped elbow," contusion Capt. Wakefield Rainey 85	Curettage of the bladder in Cystitis 351 Current topics Henry Dyer 784 Cysticercus cellulosa in man and animals 386 Cysts in feet of dog 38	Feeding of horses in Russia 115 Fees of veterinary inspectors 734, 749 Fibrolysin—an enquiry 335 — Gerald Bloxsome 350 Fibrous tumours in false nostril E. A. Phipps 143 Fistulae, Potassium permanganate in 525 Fistulae of withers, E. C. Winter 711 Flagellated organism in vulvo-vaginal eruption in a buffalo 246 Flesh diet in experimental nephritis 678 Flies, Remedies for 116, 152 Flies and infection 227 Food and feeding habits of fish 66 Follicular mange, Treatment of 502 Foot-and-mouth disease 17, at Rye 63, 66, 80, 149, Restrictions withdrawn 144, at West Hallam 154, B. of A. notice 223, at Bridgwater 242, 385, in horses 514, Report of Departmental Committee 783, 735, at Penrith 828, 829 Football—Dublin v. London 563 Foul mouth in the dog 821 Fracture, Compound, osseous suture 546 — Comminuted, of ramus of inferior maxilla—pseudo arthrosis 788 — of carpal bones, E. A. Phipps 142 — of the first rib, Two cases of Maj. W. A. McDougall 490 — of the Os pedis J. F. Macdonald 802 — of the stylo-hyoid bone in the horse 351 — tibia in 16 year old mare A. Goodall 134
Carnarvon meeting, The 57	Case of identity—foal 243	Degrees and diplomas, About 512 Demodex bovis S. N. Mitter 641 Destruction of larks 687 Determination of sex, The 829 Diagnosis, the limits of E. Wallis Hoare 1, 16 — G. Mayall 35 — symptoms J. Kerr Calderwood 52 — E. Wallis Hoare 52	Gall-sickness, injection of Trypanblau in G. T. Henderson 4 — transmission of by ticks 630
Cattle that died from fright 113	Cavalry collisions in war Lieut. T. Lishman 291	Diagnostic methods 565 Diaphragmatic hernia, Congenital W. R. Davis 261 — in the dog 690 Dick College and the City veterinary work 275, 472 Digestion of casein, The 598 Digestive troubles of the ox, James Gregg 186 — diseases of ruminants. Peter Wilson 218 — organs in the ox, Diseases of the G. Mayall 141 — E. Wallis Hoare 172	
Cell-proliferant, A new, Comfrey—Allantoin 494	Cerebral embolus, by strongylus vasorum 234	Dilatation and hypertrophy of the heart in mare, J. B. Wolstenholme 210 Dinner to Principal Mettam 412 Diphtheria in sucking pigs 204 Disease of canaries caused by bacteria of the para-typhus group 566 — in pigs—an enquiry 216, 228 — of suspensory ligament, J. Maguire 379 Diseases of animals in Gt. Britain 133 — of sheep, Clement Burston 32 Diseases of Animals—Returns 6, 14, 33, 50, 62, 79, 98, 111, 130, 144, 154, 169, 177, 199, 216, 227, 241, 257, 274, 283, 299, 311, 331, 342, 368, 371, 400, 414, 430, 440, 453, 472, 483, 496, 511, 529, 542, 562, 579, 594, 612, 625, 640, 651, 671, 688, 696, 713, 729, 748, 767, 781, 794, 799, 816, 823	
Cerebral hæmorrhage in a dog 566	Certificates—Lightning: Trimmed dogs at shows, J. G. Parr 361	Dislocation of cervical vertebrae, W. Waters 443 Distemper serum, Piorakowski's 643 Distomum hepaticum in a horse 721 Docking, Conviction for 50 Donations to R.C.V.S. 321 "Doping" race horses, J. G. Parr 361 Dr. Rutherford, why has he resigned? 158 Dublin horse show, The 66, 115 Dublin University 799	
Chemistry of traumatisms, The 309	Chloral in eversion of uterus 153		
Chloroform, New method of administering 581	Cholesteatoma in a horse's brain 246		
Chronic infectious catarrh in cattle 56	Civil veterinary work in Bengal 173		
Claim for insurance of mare, Successful 714	Claim of the R.V.C. to Government aid 673		
Claims of the vety. profession for recognition 747	Claims of vety. surgery, J. Forbes 816		
Clinical meeting, A 349	Clinical records 141		
Coal mines Bill, The 349	— H. Peele 378		
Coal mines regulations, The new 716	Coal mines Act, 1911, Inspectors: Conditions of appointment 745, 780		
Coal mines Bill, The, H. Peele 378	Cobbold, M.D. 161		
Coleman v. Twining—new trial 274	Colic due to impaction of cæcum in the horse, A. Gofton 705		
College crest appeal case, W. Kirk 260	— appeal fund 321		
— list of subscriptions 131, 158, 288, 346, 413	College finances, The—Suggestions, Sam Chambers 487		
Colloidal solutions and artificial enzymes 521	Conformation of the dachshund as a cause of paraplegia 57		
Combination, On the value of 170	Congress of R.I.P.H., Veterinary section 34		
Contagious or non-contagious abortion: claim for damages 620	Contagious pseudo-rabies 386		
Control of milk supply—Fife Local Authority and Vety. Inspectors 499	Cost of motor cars 275		
— (See Motor)	Council election, The 733		
— The significance of 817	Council meetings, The 37, 245, 457, 657		
Country practice 85	Cows and walnut trees J. Gold 356		
Cretinism, transmission of, from man to animals 214	Crib-biting case, A 714		
Crib-biting and wind-sucking Lt.-Col. J. Moore 806	— Capt. H. S. Mosley 831		
Crochmore donkey case, The 65, 99			

Gastric affections of ruminants, some queries concerning E. Wallis Hoare 135	Insurance of live stock—Germany : Switzerland : Russia : Agric. Conference, Milan 707	Medical men giving testimonials to the utility of quack veterinary medicines 831
— G. E. Nash 238	International Veterinary Congress, 1914 46, 53	Medicine as a profession 183
— J. M. Stewart 304	— The 417, 689, 801	"Megrims" in a dog, is there a remedy? Woodford 34
— W. E. Blackwell 348	— Re Guy Sutton 732	Melanosis in adult cattle 153
Gastric derangement, an unusual bovine W. Scott 308	International Veterinary Congresses, Meeting of permanent Commission 436	Melano-sarcomatosis, Secondary, in a dog 152
Gastritis and intussusception 379	Intestinal disturbance in a bull D. Forwell 358	Mendelian experiments with thoroughbred horses—scheme 626
Gastrophilus equi and "stomach staggers"—a suggestion Wakefield Rainey 545	Intussusception Lt. H. C. Stewart 290	— experiments 629
Gelatine as a hæmostatic 370	— in a foal H. S. Reynolds 358	— breeding of the racehorse 637
General anaesthesia 597	Invagination of the duodenum into the stomach in the horse 323	Mendelism 455
Generalized peritonitis, The causation of Wakefield Rainey 184	— of the stomach and spleen in the oesophagus W. Pauer 598	Method of inducing horses to swallow fluids 616
Generalized peritonitis 200	Iodine, a danger from 510	Milk and milk products W. Jackson Young 613
Glanders at Ebbw Vale collieries 33	— as sole dressing for operation wounds 509	Milk Bill, Bovine tuberculosis and A. B. Mattinson 380, 386
— in London 101	Irrigation of joint cavity J. B. Collyer 702	— Mr. Burns', to be introduced 63
— Deaths from 300, 312	Izal, Uses of 499, 627	Milk scarcity committee 334
— and £06 39, 502	Jaundice in dogs, Treatment of W. T. M. Browne 384	Milk supply of Melbourne, Victoria 80
— Diagnosis of, in dead meat 502	Johne's disease, Departmental committee to be asked for 498, 501	Mr. C. Stephenson's gift to Armstrong College 526
Glasgow Veterinary College—Opening of Session 275	Johne's bacillus, Isolation and cultivation of, and experiments on preparation of a diagnostic vaccine, F. W. Twort, G. L. Ingram 658	Mr. Kirk's appeal case, H. A. Woodruff 116
Address by Dr. David N. Knox 284	Johne's disease in cattle, Further notes on, J. T. Angwin 754	Mr. Shipley and the V.V.B. Fund 244
Presentation of medals and certificates 780	Johne's disease, B. De Vine 760	Mr. Trigger's Mayoralty 259
Glycerine, Effect of on chromogenicity of bacteria 655	Jews and phthisis L. L. Steele 687	Monstrosity, H. Thompson 118
Goat keeping in Ireland 499	Kennel Club, The, and the veterinary profession 117	— Alec. McTurk 152
Grant to Dick College 511	Kirk appeal case 457	— W. L. Gascoyne 719
Grouse disease: Report of committee 239	Laceration of mucous membrane of the trachea in a horse, Exceptional case of, R. Eaglesham 657	— A calf E. A. Phipps 142
Guttural pouch disease, Capt. Wakefield Rainey 53	Law as to personal injuries caused by animals 596	Mortality among pigs, W. J. Young 117
Hæmaturia, Bovine 720	Leaving carcasses unburied 115	Motor cars and veterinary practice H. Taylor 275
Hæmoglobinuria, Bleeding in 514	Lt.-Col. G. H. Evans, C.I.E. 369	— 277, 335, 367
Hæmorrhage, Fatal, following tooth extraction, J. McRae Frost 38	Lightning, W. N. Thompson 559	— Hugh Begg 288
Hæmorrhage into guttural pouch, Fatal 514	— Certificates 361	— H. Taylor: J. H. Parker: E. D. Johnston 304
Hæmorrhagic septicæmia, Sensitised vaccine in 370	Linguatula larvæ and peritonitis, A. S. Leese 337	— G. Upton 335
Hay fever in horses 475	Liver-rot in sheep, Researches on the treatment of, J. R. U. Dewar, MM. Raillat, G. Moussu, G. Henry 17	Multiple hæmorrhages in the muscles of the pig 203
H.M. Inspectors of horses 769	London Cart Horse Parade Society 783	Nasal polypi: necrosed bone, W. N. Thompson 359
Heredity in relation to disease J. B. Dunlop 825	L.C.C. v. Kirk, College Crest—penalty 526	National meeting, The 69
Hernia, Congenital diaphragmatic of stomach and spleen in a horse 819	London horse-omnibus, The 114	"National" meeting 1912 769
Hock joint, Open wound in E. A. Phipps 142	London's motor-busses 115	National Veterinary Benevolent and Mutual Defence Society Annual meeting, 1911 48
Hock, Severe injury to, E. A. Phipps 142	Lumbar puncture in the dog 598	— 1912 776
Holiday difficulty, The 68	Lympho-sarcoma in a dog E. Wallis Hoare 291	Necrobacillosis in the dog, H. Gray 322
— Bertrand Secker 93	Macadam and falling horses 303	Necrobacillosis, Two cases of W. Walker 350
Horse breeding and genetics 178	Maize feeding experiments 697	Neglect of a horse at a railway station 343
Horses suitable for heavy city work, J. Macfarlane 449	Mallein test and its vagaries H. G. Simpson 417	Negri corpuscles, Rapid detection of 627
How long can a horse remain under water? W. J. Moody 415	Mange in horses, Cevadilla in treatment of 278	Nephritis, a sequel of red water, L. L. Steele 305
How the veterinary profession is handicapped 639	Meat inspection in City of London 793	Newton Chambers—Award for disinfectants 184
Hydrophobia from fox-bite 215	Meat inspector in London for Australia T. Parker 580	New "Cruelty" Act, The, Lampas—shoeing smith fined 542
Impaction of the omasum, Hugh Begg 161	Medical aphorisms 180	New method of administering chloroform, J. B. Buxton 581
Imperforate hymen in cattle 530	— graduation of Prof. Woodruff 733	New skin diseases in the dog, H. Gray 103
Indian Silhadar cavalry 526		New Veterinary Association, A 441, 452
Infectious hepatitis of swine 235		Nile Campaign, The, 1884-85 4
— osteitis of horses and cattle 370		Nitrous oxide in canine practice 305

Professional Advertisements.

These will be received up to Thursday morning.
Five lines or under 2/6 (exclusive of heading): for two insertions 4/-; for three 5/-; after three 1/- each.
Each line above five—first insertion 6d; after first 3d.
Average—seven words in a line.

These Advertisements will not be inserted unless prepaid, and if replies are to be received at this office an extra sixpence must be included.

The Central Veterinary Society

A GENERAL Meeting will be held at 10 Red Lion Square, W.C. on Thursday, July 6th, at 7 o'clock. Fellows are requested to bring specimens. Agenda. Routine business: Morbid Specimens: Impromptu Discussion.

HUGH A. MACCORMACK, Hon. Sec.

South Durham & North Yorkshire V.M.A.

A MEETING of this association will be held in the Imperial Hotel, Darlington, on Friday, July 7th, to consider the question of Professional Fees. All veterinary surgeons in the district invited.

Locum Tenens

M.R.C.V.S. who has just sold his practice, and is disengaged for two months, would be pleased to act as above. Good testimonials and references. Address: 1071 V.R., 20 Fulham Road, London, S.W.

For Disposal

VETERINARY practice for sale in Glasgow, old established, grand opening for energetic man, full particulars. Address, Matt. White, M.R.C.V.S., 386 Gt. Western Road, Glasgow.

Wanted

QUALIFIED Assistant for London practice. Sign bond. State age, salary required, and experience. Address, 1072 V.R., 20 Fulham Road, London, S.W.

Wanted

BY class C student, up at Xmas, situation as assistant or improver for the summer vacation. Address, 1073 V.R., 20 Fulham Road, London, S.W.

Surgery to Let

IN the West End of London—well fitted and furnished compete, drugs, etc. H. Dyer, 66 Brompton Road, S.W.

Qualified Assistant

WANTED about the end of July a thoroughly practical qualified assistant for town and country practice. Permanency to suitable man. State age, salary required, and references. Address, 1074 V.R. 20 Fulham Road, London, S.W.

As Improver

M.R.C.V.S. will be pleased to recommend a student as improver for three or four months. Live in or out. and make himself useful: good horseman, and industrious. Address, 1075 V.R., 20 Fulham Rd, London, S.W.

Mallein and Tuberculin

MEMBERS of the Profession may obtain Mallein and Tuberculin on application to the Principal, Royal Veterinary College, Camden Town N.W., on the following terms: in bottles, 6d. per dose. Minimum quantity supplied, two doses. In hermetically sealed tubes, containing one dose each (specially suitable for use abroad) 1s. per dose.

G. H. PICKWELL, M.R.C.V.S.

LOCUM TENENS,

Makes a speciality of above duty.
Disengaged.

73 Victoria Mansions, South Lambeth Road, S.W.

HUGH R. SINGLETON, M.R.C.V.S.

LOCUM TENENS.

Disengaged July 7th,

44 St. Michaels Road,
Bedford.

L. A. F. DAWSON, M.R.C.V.S.,

LOCUM TENENS,

Disengaged July 1st,

43 Denning Road,
Hampstead, N.W.

Assistant

WANTED in the country a practical assistant, to live in. Must be good dispenser. Apply, giving full particulars, to 1079 V.R., 20 Fulham Rd., London, S.W.

As Assistant

CLASS C student, up in July, is desirous of the above position during vacation. Three years practical experience in a large mixed practice prior to entering coll. Capable of fulfilling all duties. Address 1076 V.R., 20 Fulham Road, London, S.W.

Locum Tenens

M.R.C.V.S., practical, competent, good references, ab-stainer. For terms and particulars apply, 1077 V.R. 20 Fulham Road, London, S.W.

As Assistant or Locum

CLASS D student seeks situation as above. Either town or country. Excellent references. Address, 1078 V.R., 20 Fulham Road, London, S.W.

Wanted

GENUINE town and country practice, returning £600 per annum or over, hunting essential. Devon or adjoining county preferred, strict confidence. Address 3107 V.R., 20 Fulham Road, London, S.W.

As Locum or Assistant

FINAL-YEAR student (24); competent locum; several years experience; excellent references. Disengaged July 20th. Address, 2107 V.R., 20 Fulham Rd., London, S.W.

All communications respecting advertisements should be addressed to

H. & W. BROWN. 20 Fulham Road, London, S.W.

Tracheotomy Tubes

MISS JONES, successor to F. B. Jones, M.R.C.V.S., still continues to supply the Special Tracheotomy Tubes patented by her late father. Special terms to Veterinary Surgeons. Address, 86 Kimberley Road, Leicester.

Wanted

SITUATION as dispenser and kennel man, three-years experience and excellent references. Write, stating wages given, to P. Bowyer, 134 Mansfield Rd., Derby.

Assistant Wanted

FOR town practice. State age, references and salary required. To live out. Sign usual bond. Address, 1107 V.R., 20 Fulham Road, London, S.W.

As Locum

ADVERTISER, unqualified, is open to engagements as locum. Well up in all branches. Highest references. Disengaged July 1st. Address, 4107 V.R. 20 Fulham Road, London, S.W.

For Sale

DEATH VACANCY. Staffordshire, horse and canine practice, situated in centre of town. Receipts £250 per ann. but could be greatly increased. Good house, kennels and forge; working expense small. Good introduction. Will be reasonably disposed of to immediate purchaser. Address, 3061 V.R., 20 Fulham Road, London, S.W.

Wanted

MARRIED assistant (qualified or unqualified) no family, by middle of July. To live on premises, house furnished, abstainer preferred. Must be good book-keeper. Address, 3064 V.R. 20 Fulham Road, S.W.

For Disposal

GENUINE old established town practice and shoeing business in Lancashire. Good premises, with every convenience for doing a large and profitable trade, carried on successfully for many years by owner, who is retiring. Address, 4042 V.R., 20 Fulham Road, S.W.

For Sale

OLD established, mixed country practice, average over £5 weekly last three years: suit young man. Address, 1066 V.R., 20 Fulham Road, London, S.W.

Chlorodyne

FOR SALE, a large quantity of Chlorodyne, full strength, B. P. 1885, at 2/- per pound. H. J. Pratt, Wholesale Druggist, Cleckheaton.

CHEAP BOTTLES.

A large quantity of named medical bottles (these have various chemists' names on and washed ready for use)
2oz., 3oz., 4oz., 6oz. and 8oz. at 5/6 a gross.
10oz., 12oz., and 16oz. at 7/- a gross.
Cash with order. Carriage paid on £3 orders within 70 miles, and on £5 orders any distance.
Other bottles and jars quoted for.

F. NEEDHAM,
Beaconsfield Road, Acton Lane,
Chiswick, London, W.

Practice Wanted

COUNTRY practice, Cheshire or neighbouring county, Capital at command. Particulars in confidence. Address, 2062 V.R., 20 Fulham Road, London, S.W.

Wanted

SMALL country practice or nucleus, near market town, where fowls and swine may be kept. Replies to Veterinary, c/o Shelley's, Gracechurch St., E.C.

Assistant Wanted

FOR Country practice, to live in. Must be practical, and have good reference. Address, giving full particulars, 2057 V.R. 20 Fulham Road, London, S.W.

The Glasgow Veterinary College,

INCORPORATED.

Principal: **JAMES MCCALL, F.R.C.V.S.**

Session, 1911-1912.

This College is under the management of a representative Board of Governors and is recognised as a Central Institution under the Education (Scotland) Act, 1908. A complete course of instruction is given in the subjects of examination for the Diploma of the Royal College of Veterinary Surgeons, and the field for clinical observation is unsurpassed. The equipment of the College is being extended and modernised. Students are eligible for bursaries granted by Secondary Education Committees of the Counties and certain Burghs of Scotland.

The Matriculation Examination conducted by the Educational Institute of Scotland for intending Students will be held on 6th, 7th, and 8th July, and 7th, 8th, and 9th September.

Next Session commences on Wednesday, 27th Sep. 1911

Further particulars may be had on application to the Principal, or Alexander Russell, 54 West Nile Street, Glasgow, Secretary.

"MAGNUM" PESSARIES.

(HEWLETT'S)

"Magnum" Pessaries are prepared with a medicated non-oily base which is both effective as a Uterine Antiseptic and of special benefit in Parturition both in Cows and Mares.

A "Magnum" Pessary should be inserted directly after parturition in order to maintain the Uterus in a healthy state. It can be inserted with the greatest ease and will keep the parts in a thoroughly antiseptic condition for a lengthy period.

Alkaline "Magnum" Pessaries have recently been recommended to neutralise excessive acidity of Vaginal secretion.

"Magnum" Pessaries are supplied according to various formulæ as below, and Veterinary Surgeons' own formulæ can be made up as required.

"Magnum" Pessaries.		Doz.	12 doz.	Doz.
"	Acid Boric 2 drms.,	84/6		4/-
"	Acid Boric 2 drms.,	6/-	"	5/6

Saloform Pessaries.

The New Uterine Antiseptic

Highly recommended by many eminent
Veterinary Surgeons.

PRICES: Ordinary Strength, White.

4/6 per doz. 48/- per gross.

Extra Strong, Yellow.

6/6 per doz. 72/- per gross.

Sole Proprietors—

HARKNESS, BEAUMONT & CO.,

Wholesale Chemists,

EDINBURGH.

Veterinary Surgeons have for long keenly felt the want of something which could be used with good results as a Uterine Antiseptic and which at the same time could be quickly and easily administered. After many trials, and with the kind co-operation of some able Veterinary Surgeons of great experience in parturition cases, we have succeeded in producing

a Pessary made with a non-oily base which does its work efficiently and at the same time is non-irritant—in fact, soothing in its effect. They are of great use in parturition in cows or mares; and if administered immediately after parturition they will keep the Uterus clean and healthy, and prevent the after-birth becoming foul.

Veterinary Surgeons in various parts have highly recommended them, and there is an increasing demand for both kinds.

Customers are requested when ordering to state which kind they prefer.

A RECENT UNSOLICITED TESTIMONIAL.

AINSWORTH WILSON, ESQ., F.R.C.V.S.,
writes:—

"I have used the Saloform Pessaries supplied by Messrs. Harkness, Beaumont & Co., of Edinburgh, with good results in various diseases of the genital organs, both in mares and cows, more especially after parturition. They are particularly useful in retention of the afterbirth, with septic complications. It is often impossible to attend more than once a day to irrigate the uterus; in such cases it is good practice to leave one or two of the "extra strong" pessaries *in situ*. I have found them an excellent substitute for Iodoform and other well known non-irritating antiseptics. I feel justified in recommending them to the profession.

Witham, Essex.

THE VETERINARY RECORD

A Weekly Journal for the Profession.

EDITED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1199.

JULY 1, 1911.

VOL. XXIV.

THE LIMITS OF DIAGNOSIS.

Recently Mr. Wallis Hoare has revived the discussion of this question, which, though an old one, will well bear repetition from time to time. It is a subject regarding which the education of the profession is yet far from complete, and that of the public has hardly been more than begun.

There was a time when the majority of practitioners habitually over-estimated the clinician's powers of accurate diagnosis. Thanks partially to the labours of pathologists, and perhaps even more to the persistent teaching and recorded experience of a few open-minded clinicians, we can safely say that, as a profession, we appreciate the limitations of our diagnostic powers much more clearly than did our forefathers.

Most practitioners nowadays will be in substantial agreement with Mr. Hoare in the many instances he cites of the difficulty, and frequent impossibility of diagnosis of cases, many of which are among the commonest met with in practice, and the unreliability of not a few of the symptoms once regarded as diagnostic. In one sense our advances in clinical medical and surgical diagnosis during recent decades have been disheartening, for they have very largely consisted in the recognition of errors; but, nevertheless, one great general advance has been made. It is true that in very many cases a skilled clinician of the type of Mr. Hoare is little more likely to reach an accurate diagnosis than the practitioner of thirty years ago: but he is certainly far less likely to confidently arrive at and act upon a wrong one.

There are still a few practitioners who retain unbounded faith in their individual diagnostic powers, but their number is decreasing. There are a larger number, unfortunately, who have not yet emancipated themselves from observance of the popular tradition requiring a clear immediate diagnosis from every veterinary surgeon, and here the difficulty comes in. So long as the public requirements in this respect remain as at present, every practitioner—especially if not yet firmly established—is daily placed under a strong temptation to fall in with them, and very few men fully resist it. This much should be remembered—that the public, who were taught to expect infallibility in diagnosis by generations of doctors and veterinary surgeons in the past, will retain the same expectations until slowly taught otherwise by practitioners of the present and future. A great deal at least of the difficulties between the medical and veterinary professions and the public have been made, and can only be removed, by the professions themselves.

A CASE OF EQUINE TUBERCULOSIS.

The subject, a brown cart gelding, No. 1015, was purchased May, 1909, and was then five years old. Previous to this the horse worked on the farm where bred. The horse was worked in our department collecting refuse from house to house. On November 10th, 1910, the stableman reported that the horse was off his feed and blowing badly. This was the first time he was noticed ill since being purchased. On examining the horse his respirations were 30 per minute, temperature 102 F., and pulse 50, I was unable to detect any definite symptoms of pleurisy or pneumonia, and I entered the case up as a slight feverish cold.

I had the horse placed in a loose box and gave $\frac{1}{2}$ lb. Mag. sulph. and a fever drench consisting of Spts. æth. nit. and Liq. ammon. acet. The drench to be repeated morning and night. Linseed and bran mash, and a little long hay were given instead of the ordinary corn ration. After two days the temperature was 101 F., but the pulse and respirations were unchanged. The least exertion on the part of the horse, such as getting up from the recumbent position, increased the respirations for a short time.

The horse had been in the stable for four weeks and the symptoms were so irregular, and nothing definite detected as to the cause, it was decided to test him with tuberculin.

On December 22nd I injected into the near side of the neck 3 c.c. of tuberculin, the site of injection not being previously prepared in any way, no antiseptic precautions being taken with regard to the skin. Twenty-four hours after injection there was a large sharply defined local reaction which later increased in area, especially as its most dependent point. The local swelling measured eleven inches by five inches. Following the injection the temperature was taken every two hours up to the 36th hour, when the temperature has again fallen to 102 F., the maximum temperature being 105.6 F. Chart No. 1 shows the change in temperature following the injection of the tuberculin.

The local reaction was so large and so unexpected that I suspected it was due to some local injection and not to the tuberculin, in fact I attributed the local reaction to want of precaution on my part in not properly cleaning and disinfecting the skin prior to and at the site of injection. The local swelling gradually decreased in area and depth and disappeared about the fifth day after.

At the usual half-yearly weighing of horses in July, 1910, this horse weighed 17 cwt., and as he now appeared to lose flesh daily I had him again

weighed on January 3rd, 1911, and he turned the scale at 12 cwt. 1 qr.

On January 9th I again injected the horse with tuberculin. This time I shaved a spot about four inches square on the middle of the neck on the off side, I had the part then washed with soap and water, dried with cotton wool soaked in ether, and following this the part was further antiseptized with Tinct. iod. The hypodermic syringe was boiled before use, and the tuberculin injected subcutaneously in the centre of the disinfected spot. The temperature was taken after injection at intervals of two hours up to 64th hour.

Chart No. 2 shows the change in temperature following the 2nd injection. Ten hours after injection a local swelling appeared at the site of injection and continued to increase up to the 24th hour when it gained its maximum size, then measuring 11 inches long by seven inches across, and its depth I should judge to be about one and a half inches.

On January 11th, 1911, the horse weighed 12 cwt. 14lbs. On January 17th his weight was 11 cwt. 3 qrs. 21lbs, and on January 24th 11 cwt. 3 qrs. 7lbs.

As we now had no doubt about this horse being affected with tuberculosis, and as he continued to lose weight daily, it was decided to have him destroyed.

Post-mortem Examination. The heart, liver, bowels, and kidneys appeared normal. The spleen was covered with tuberculosis nodules. The accompanying photograph No. 1 gives one only a hazy idea how badly it was affected. The lungs were enormously enlarged, and when the thorax was open they appeared to completely fill it. They appeared exactly like lungs which are artificially inflated outside the body. The pleura, both on the chest walls and lungs, was smooth and glistening. I had the heart and greater part of the trachea detached from the lungs, and the latter weighed. They weighed 77lb. While at the slaughterhouse I had three sets of cart horses lungs weighed, and they averaged 19lb each, therefore I conclude the lungs from this horse must have increased at least 55 to 58lb above their normal weight. On further examination of the lungs I found the mediastinal lymphatic glands apparently normal and showing no signs whatever to the naked eye of being affected. The lungs were of a cream colour with red streaks at intervals through them, and on palpation felt hepatized. The cream-coloured material in the lungs was of a waxy consistency. On section the lungs appeared more or less completely filled with this cream-coloured material, in fact there was a very small amount of real lung tissue remaining. Microscopic examination of the lungs showed giant cells and tubercle bacilli. Micro-photographs No. 2 and No. 3 show high and low power microscopic appearance of cross section of the lungs.

BRENNAN DEVINE.

Veterinary Department, Birmingham.

UNUSUAL CASE OF ANTHRAX IN A MARE.

The following case presents some rather uncommon features, and I hope it may prove of interest to your many readers.

On Saturday afternoon, June 17th, I was requested to see a four-year-old breedy harness mare, the property of Mr. John Forth, of Brown Hill, Burnley. The mare was in a loose box, and was only noticed to be off her feed in the morning, but as she made no improvement as the day went on my services were requisitioned about 4 p.m.

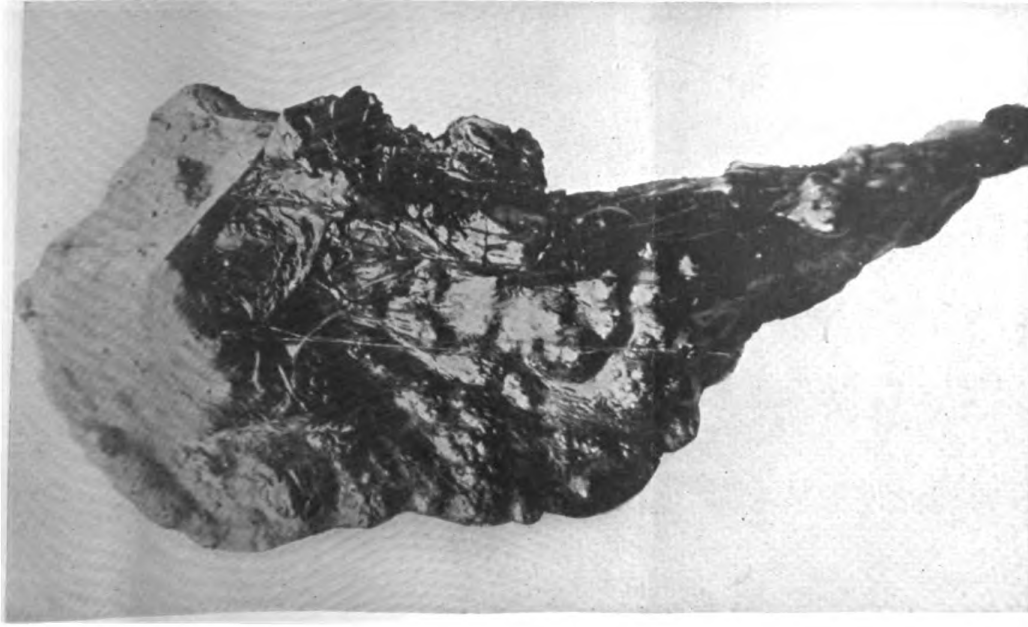

I found the mare dull and dejected, with a slight nasal discharge, breathing slightly disturbed, pulse 96, temperature 104 3-5th. Auscultated chest but could discover no abnormal sounds, percussion caused no inconvenience; extremities normal heat, and had every appearance of an every-day case of hyperpyrexia. A fever draught was administered and a few fever powders left. I told my client I would call again in the morning.

Sunday, about 9 o'clock, I found a marked change for the worse. Breathing was laboured, dull and dejected, cold ears and extremities. Injected conjunctiva, pulse imperceptible, temperature dropped to 102, refused all food and water. I administered a stimulating ball, and upon raising the head to administer a draught she dropped like a log and had some difficulty in regaining her feet. I applied mustard to chest and rubbed it well in myself, but to my astonishment she showed no feeling whatever. I had her head brought to the box door and secured there, and had her legs bandaged.

I informed my client it was a case that presented some rather unusual features of a grave nature, and was certainly somewhat puzzling. I dare not attempt to drench again, but promised to look in later, about noon, to administer another stimulating ball but I had not the opportunity, as the groom called about 12 o'clock noon to say the mare was dead.

I remarked it was an uncommonly interesting case, and made arrangements to have a post-mortem examination, which took place about 1.30 in the afternoon.

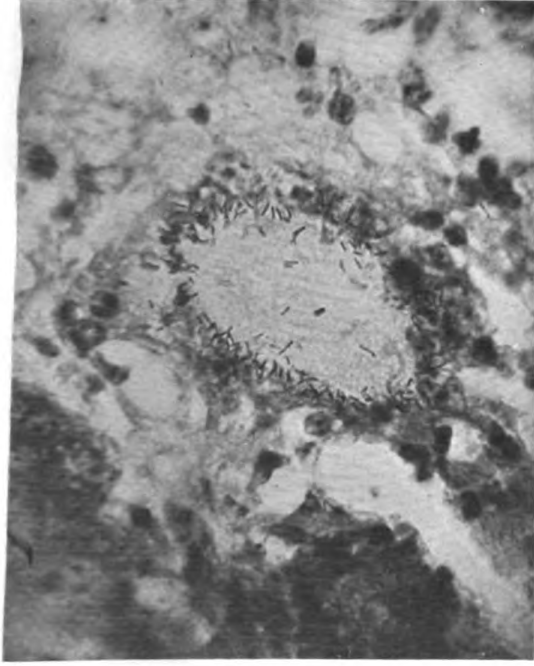

Upon opening the abdominal cavity there escaped a great quantity of straw-coloured fluid, and upon removing the viscera my eye caught a globular looking body which proved to be an ovary, ruptured, showing a large black clot of blood; upon the longitudinal muscular band of the great or double colon there was a quantity of gelatinified serum. My suspicions were at once aroused that I had a case of anthrax to deal with. I then came to the spleen, which was very much swollen and enlarged, weighing 9½ lbs. I immediately gave orders to proceed no further with the autopsy, and to leave the carcass where it was until further instructions. I collected some blood and made the usual smear, stained with methylene blue and examined with a microscope, and had no difficulty in finding swarms of anthrax bacilli.

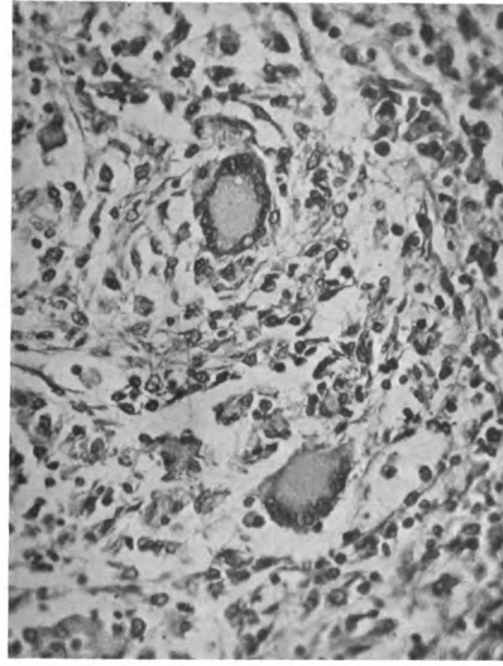

SPLEEN.

EQUINE TUBERCULOSIS.

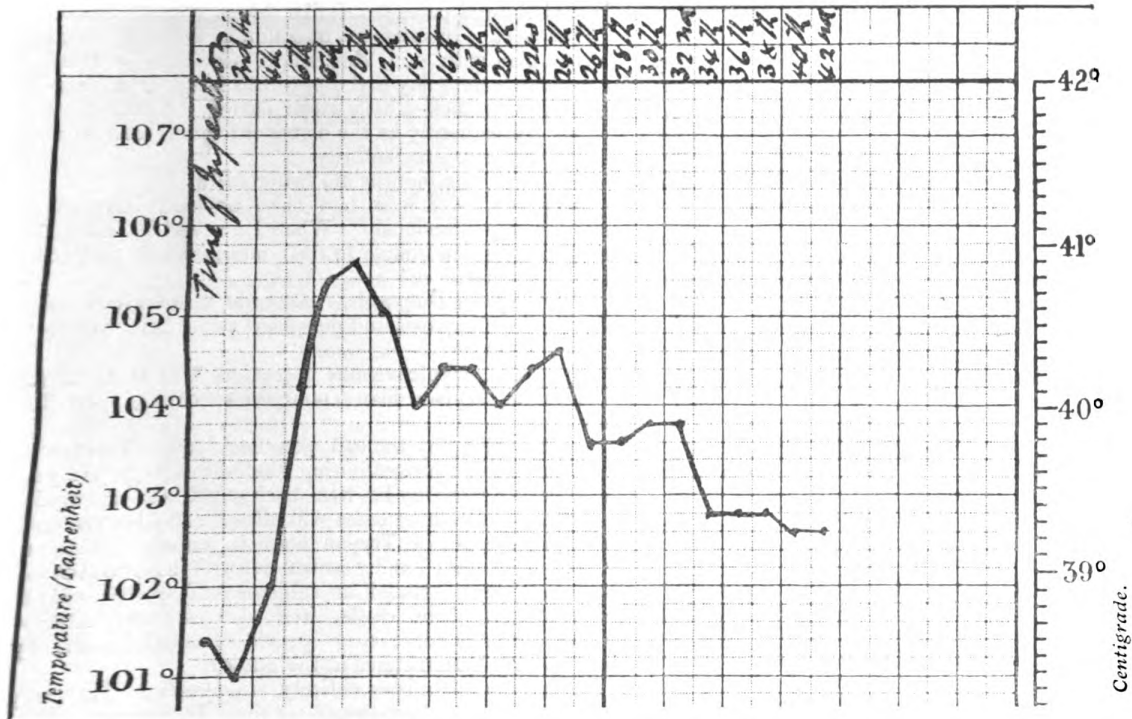

Note by Mr. Brennan De Vine, F.R.C.V.S.

3. Cross section of lung. Low magnification.

Tuberculosis. Brown Gelding, No. 1015. Chart I.

Tuberculosis. Brown Gelding. No. 1015. Chart II.

I at once acquainted the police, and as the case was in the Borough the Corporation veterinary surgeon took it in hand.

The history of the mare is as follows:—She was bred by the owner, and only brought up from grass two months ago, put into the breaker's hands, and had only been working three weeks when taken ill. Upon enquiry as to her food, and whether she has had any foreign hay etc. I was informed she had not, and so the case remains a mystery as to its origin.

The foregoing case only goes to prove, in my opinion, the importance of following up fatal cases that prove perplexing to the practitioner, and I am firmly convinced there are many such cases that escape observation and never come to light. I think it is over twenty years since I had a case of anthrax in the equine species, and never to my knowledge have I ever before seen one prior to death.

JOSEPH H. CARTER, F.R.C.V.S., F.R.S.E.

Burnley.

THE RESULTS OBTAINED BY THE INTRAVENOUS INJECTION OF TRYPAN BLAU IN THE PLASMOSIS OF DOMESTICATED ANIMALS WITH ESPECIAL REFERENE TO GALL SICKNESS.

In *The Veterinary News* of May 6th Government Veterinary Bacteriologist Bevan, Southern Rhodesia, mentions in his report for the year ending December 31st, 1910, that Trypan blau has no curative action on the disease known as "Gall-sickness" due to the presence of "*Anaplasma marginale*" and "*Piroplasma mutans*." This is not, however, my experience, as the following cases indicate:—

Case I. Red heifer, one and half years old.

Symptoms. Off feed, temp. 105 F., salivating freely, tucked up, staring coat, constipation and lachrymation; membranes tinged with yellow; nervousness, brain trouble, indicated by a glassy fixed stare of eyes, and moaning fiercely when handled; pulse quick, small, and aggravated.

Microscopical Diagnosis. Examination of the blood revealed when stained by Giemsa the presence of *Anaplasma marginale* with an occasional specimen of the *Piroplasma mutans* and *Anaplasma centrale*, Poikilocytosis, and Basophilia.

Treatment. Injected 200 c.c. of a 2% solution of Trypan blau intravenously; also administered 3ss. Calomel, followed by 3viii. Mag. sulph.

The following day there was no apparent difference in the general appearance, save that the membranes and skin were deeply tinged with blue, and the heifer had begun to eat a little. Temp. 105.

The next day she appeared a little brighter; temp. 104. I administered 3ss. doses of Quinæ sulph. twice daily. Microscopical examination of the blood stained with Eosin-Azur. revealed only a few anaplasms. The heifer subsequently did well.

Case II. Black and white two-year-old heifer.

Symptoms. Resembling Case I. in every way. Temp. 104.2.

Microscopical diagnosis. Stained by Eosin-Azur showed parasites similar to previous case.

Treatment. Intravenous injection of 200 c.c. 2% Trypan blau with 3viii. Mag. sulph. per orem. The temperature next day had dropped to 104, and she had begun to pick a little green barley. I did not see her subsequently as the owner informed me she was doing quite satisfactorily.

Case III. Six months old heifer calf.

Symptoms. Off feed, had been noticed unwell for three days previously. When I arrived I found her prostrate and unable to rise; membranes pallid and temp. 103.

Microscopical Diagnosis. Anæmic condition of blood; Poikilocytosis and *piroplasma mutans* strikingly evident.

Treatment. Intravenous injection 100 c.c. 2% solution of Trypan blau; nourishing diet, gruel, milk, etc.

On the third day the calf was decidedly better, and gradually improved during the following days until on the fifth day he was discharged as cured.

I think these three cases will afford ample proof of the usefulness of Trypan blau in cases where "marginal points" and "central points" are microscopically demonstrated in subjects affected with "gall sickness" in cattle, and also when *Piroplasma mutans* supervenes—provided a sufficiently large dose is administered at the outset.

Trypan blau has been entirely successful in my hands in all the plasmoses other than *P. parvum* of domesticated animals, viz., *piroplasma canis*, *piroplasma equi*, and the previously described "gall-sick" parasites.

G. T. HENDERSON,

Govt. Veterinary Surgeon.

Kokstad, E. Griqualand.

THE NILE CAMPAIGN, 1884-85.

A correspondent writes as follows;

The recently published "Autobiography" of the late Lieut.-General Sir W. F. Butler bears in a very interesting manner on the Veterinary Report of the Campaign in the Soudan in 1884-85, now appearing in your pages.

It is noteworthy that the Principal Veterinary Surgeon was not the only member of the Staff who who was refused permission to accompany Head Quarters, and unable to obtain access to the authorities. I enclose herewith the extracts in question:

* * * *

"There was no use in deploring the time already lost, but to get the last mile of distance for our boats out of every remaining day, and save the first and last glint of daylight for our work in the time that yet remained to us, did seem to me an object worth every risk that could be run to win it. It was in this effort that the telegraph beat me. It had been at work from Wady Halfa to Dongola. It was decreed that I was not to pass beyond the head of the Third Cataract! I was not to see the Commander-in-Chief! I must go back to Dal! What I wrote that afternoon in my boat in the

middle of the Nile, somewhere in the broad water below the Isle of Argo, I could not now recall, but I remember that my pencil flew over the blank backs of some nine or ten large Egyptian telegraph forms, as no pen or pencil of mine ever went before or since. I handed the packet of tissue sheets to the messenger to give to Lord Wolsey in Dongola and then turned down stream with, I think, the heaviest heart and saddest brain I had ever known in my life."

* * * *

"When I reached Korti on 4th January, the advanced portion of the Desert Column had already left that place for Gakdul, a watering place half-way on the road to Metemmeh, but the number of camels to mount and carry supplies, even for a force of 2000 fighting men, was totally insufficient, and it was necessary to unload the camels at Gakdul, form a depot there, and bring the animals back again to Korti for another load of supplies. Thus the leading portion of the force left Korti on the 30th December, arrived at Gakdul after a forced march on the morning of the 2nd January, started again for Korti on the same evening, and reached that place at noon on 5th January, having covered a total distance of 196 miles in 5 days and 21 hours. This march sealed the fate of the Desert Column. The camel is a much enduring beast of burden, but 196 miles in 141 consecutive hours was more than even he could bear. It was pitiable to see these poor beasts dragging themselves to the river on the 5th, 6th, and 7th, many of them falling dead at the water's edge as they tried to drink. The main body of the Desert Column finally left Korti on 8th January, reached Gakdul on the morning of 12th, and at 2 p.m. on the 14th January started on the remaining 90 miles to Metemmeh. The camels were now completely done."

* * * *

"The march from Meroë to Dongola, 200 miles, in end of May and early June, was the hottest day that had ever fallen to my lot. I had to pick up at each summer station in succession—Korti, Tani, Kurot, Abu Gus, and Handak—the horses, guns, camels, and transport of the whole force, all the remnants of the Desert Column that could not be put into our old boats. I can never forget the last day's march from Handak to Dongola. A desert blizzard blew straight in our faces, hot, strong, and bitterly biting with the grit sand and small stones that it hurled in our teeth. Camels and horses often turned aside unable to face it. We had orders to leave the camels behind us. The wretched animals that had been in the Desert Column were spectres, mere bones and sores. As they fell they had to be shot by the rearguard."

Two-thirds of the camels collected at Tani and Kurot thus perished. I had taken the precaution of feeding up my camels at Meroë for weeks before the move, giving them the large stores of grain laid in in anticipation of the autumn campaign, and ordered to be destroyed on evacuation, and although the camels had a double distance to travel to reach Dongola, I lost only one or two on the march down. But the strangest part of the proceeding

was that the General Officer in command of the force thought fit to report me to the Commander-in-Chief for not having obeyed the orders to destroy the grain by fire. Called on for an explanation, I replied that although I had departed from the letter I had still observed the spirit of the order, inasmuch as I had used the grain as extra fuel to keep the ebbing fire of life in my unfortunate camels, and while expressing regret at even the seeming departure from the letter of the regulation, I added that my penitential feelings were somewhat mitigated and consoled by the reflection that while the camels of the censorious Commander had lost some 80 per cent. of their numbers on the short march, mine on the longer route had not lost above two per cent."

ABSTRACTS FROM FOREIGN JOURNALS.

ADRENALIN IN PURPURA HÆMORRHAGICA.

Prof. Schlampp, reviewing the various methods of treatment adopted for purpura hæmorrhagica, concludes that in view of the conflicting reports of the use of the various and somewhat costly sera, and the general disappointment that has followed the employment of drugs supposed to possess a "specific" action—such as iodine and the silver compounds—reliance should be chiefly placed upon a purely symptomatic treatment.

As the most marked clinical symptoms in purpura hæmorrhagica proceed from alterations in the medium-sized and small bloodvessels, the increased permeability of whose walls cause extravasations into the soft tissues, Schlampp holds it important to prevent, or at least to limit, this tendency to extravasation. This can only be accomplished therapeutically by drugs which cause powerful and enduring contraction of the lumen of the vessels. Schlampp is not convinced that the two old vasoconstricting drugs, hydrastis and ergot, are beneficial in this direction in purpura hæmorrhagica, and suggests adrenalin in preference.

The earliest, and so far as Schlampp is aware the only, employment of adrenalin in purpura hæmorrhagica was in 1906, when Payron tried it, giving doses twice daily by the mouth. Since then, Schlampp thinks, this method of treatment has been forgotten; but during the past year he has treated some cases of the disease—some of them being of medium severity, and some very serious—with adrenalin. He now describes his method and its results.

The only adrenal preparation Schlampp used was the *Solutio adrenalini hydrochlorici* Takamine, 1 c.c. of which represents one milligramme of adrenaline. Schlampp used 2 c.c. to 4 c.c. of this solution diluting it with sterilised water up to 10 c.c., and injecting this dose subcutaneously. He repeated this injection every second day, and as a rule four or five injections were necessary.

Disturbances of the general condition, or undesirable results at the site of the injection, were never

observed. The first results of the injections which appeared were of a somewhat surprising nature. The temperatures of horses which registered from 104 F. to 105 F. when injected, sank to complete apyrexia within 12 to 18 hours after the injection; and this striking event was repeated regularly and without exception in every feverish horse that was injected. The afebrile condition lasted for different periods of time, but was never shorter than two days; and in cases when a febrile temperature recurred, the next injection again caused prompt remission. The method by which this reduction of temperature is effected does not seem quite clear. Schlampff suggests as a possible explanation that the effect of the adrenalin upon the circulation may influence tissue change and heat production. In every case the attainment of apyrexia may be regarded as a good sign; seeing that as a rule in purpura hæmorrhagica the earlier a high temperature appears, and the higher it ascends, the more serious is the case.

The effect of the adrenalin upon the œdematous swellings and the ecchymoses of the mucous membrane was also a favourable one. Fading of the petechiæ was first observed, and this took place fairly quickly. Swellings, which, when treatment was commenced, were already present in the cutaneous or subcutaneous tissue retrogressed rather more slowly, but vanished within three to five days, perhaps leaving a mere trace of their pre-existence at the end of that time. Schlampff thinks it doubtful

whether a quicker resorption of the swellings than this is really desirable. In untreated cases of the disease, at least, the often-seen spontaneous sudden disappearance of the swellings is not a good sign.

Though in not a few of Schlampff's cases, the swellings at the commencement were very extensive, tense, and painful, yet the much-feared processes of mortification completely failed to appear. Now and then, during the period of the injections, new œdematous swellings appeared; but these did not assume formidable proportions, and soon disappeared again.

Schlampff gives no notes of any single case, and does not say how many cases he has treated or if any have been unsuccessful; but simply remarks that the number of his favourable cases is far too few to permit a definite judgment of the value of the treatment. He fully commends it, however, for more extensive trial by the profession. Should it prove satisfactory, it remains to be proved whether other adrenal preparations, as paraneprhrin, epinephrin, etc., will be found as useful as adrenalin; and it is also possible that, with regard to adrenalin itself, the dosage may be found capable of improvement. Schlampff himself is satisfied that adrenalin is without danger in the doses he has employed; but is evidently inclined to suspect that so far his dosage has erred on the side of prudence, and that further experience may justify an increase of dose in all cases.—(*Münchener Tier. Woch.*)

* As Diseased or Exposed to Infection

NILE EXPEDITION 1884-5.

(Continued from p. 806.)

Report by Veterinary Surgeon E. E. BENNETT, on Camels and their diseases during the Nile Expedition.

The Land Transport, almost wholly performed by camels, the fighting force (the Camel Corps) were also mounted on these animals—a portion of one cavalry regiment was employed in addition; mules and donkeys were used at some of the cataracts for the portage of stores.

Remounts.—The purchases of camels were chiefly made north of Assouan and south of Cairo. No Delta animals to be bought, as it was said they could not stand the climate of the Soudan. How far this may be true I am not prepared to state, not having been there during height of summer. Combatant Officers were mainly employed for this duty, some of whom were evidently of doubtful experience, as was proved by the large number of very young camels which came into the depots. At Assouan, owing to a report sent in by me on this point, a board was called, and it was found that at the time there were 95 camels three years old and under, 45 four

years old and under; and many other four year olds, although so young, were considered by the board as fit for issue, being fairly well-developed, which is more than could be said for the remainder. The mistake arose probably from the inability of the purchaser to distinguish between permanent and temporary incisor teeth; but the infantile appearance of the three year olds should have been sufficient evidence to decide their rejection; animals of this kind are only a useless encumbrance and profitless investment. Further, on the march to Gakdul from Korti, one-third of the camels which died or fell out *en route*, were remounts issued at Korti in exchange for animals worn out with the length of the march up country. This heavy casualty list among the remounts was in great measure due to their extreme youth, and their consequent inability to perform the most ordinary work.

There are many varieties and breeds of camels. For war purposes, however, they were divided into two sections only, viz., the riding or trotting camel, and the baggage or non-trotting; the former employed for mounting the fighting force, the latter for transport, including Royal Artillery, Field Hospital and Bearer Companies. I will briefly allude to the different varieties which came under my immediate notice.

The Aden camel. Some few hundred were shipped from Aden to Kosseir (on Red Sea), and from thence marched *via* Kenah to Assouan (237 miles). They are light, clean-bred animals, chiefly used by us for riding purposes, although in their own country mainly employed for transport. They are of a uniform colour—dun—with short, fine coats, rendering them less liable to parasitic skin affections, and even when once attacked are treated in consequence with greater chance of success. This point can hardly be too highly esteemed, where a large number of animals are congregated together. They are quick-stepping, and from my experience of them will endure fatigue better, and subsist on less food than the Egyptian camel brought up in a cultivated district. They are unsuited to a cold climate, but are said to be good at hill work.

The Bishareen—bred by the tribe of the same name, are mainly of the riding class, and unsuited to carry heavy loads; they are generally of a whitish colour. Being desert camels, it is claimed for them that they can withstand the privation of thirst, without harm, for several days. Many of this class were purchased, and succumbed under the pressure of work imposed upon them.

The Kabbabish take their name from their breeders; they are found in and around the Bayuda Desert, and were principally hired when our own transport failed. They are larger and stronger than the Bishareen, are accustomed to feed largely on grain, but live by feeding on the mimosa tree and the coarse desert grasses. They are, in consequence, very valuable where corn is not procurable; but time (which we could ill afford) is necessary to admit of the grazing system being carried out.

The Ghizeh—bred in the district of that name, which is in neighbourhood of Cairo, near the Great Pyramids. Being half Desert and half Delta animals they are large and very powerful, well suited for all transport purposes. They are much esteemed by the Arabs, and command a higher price in the market than the pure Delta.

The Delta, almost wholly burden camels, powerful and slow-paced. Being bred in cultivated districts, they are unable to withstand the want of water for any period without suffering commensurably; several found their way into the service of the Expedition, although their purchase was prohibited.

The Assiout camel, not a special breed, but a mixture apparently between the Ghizeh and Delta was, in my opinion, the most valuable animal for transport purposes employed in the Expedition.

Age of Remounts.—A camel may be said to be in its prime between 7 and 12 years old. The endeavour should be to purchase about this age, and although from paucity of animals one may be obliged to take those which are younger or older, none should be bought without at least showing four permanent incisors ($5\frac{1}{2}$ years), and preference should be given to those over 12 years rather than those under $5\frac{1}{2}$. A full-mouthed camel possesses six incisor teeth in the lower jaws, and two sets of tushes (two on either side), one set being secondary or rudimentary. In the upper jaw three sets of tushes (three on either side), one primary, and two secondary or rudimentary sets, situate one on each side of the large or primary tush. Molars twenty-four, six on each side of each jaw. It is unnecessary to again allude to the numbers of young camels which were purchased for the Expedition.

Size.—Well-proportioned, medium-sized, compact, short-legged animals are the most serviceable. A considerable experience (a good "eye") is indispensable in the purchase of camels, as in all other animals.

Other points.—Pay attention to the eyesight, as old camels frequently suffer from partial or total blindness. The girth to be deep, the elbows to be set out, well away from side of chest to prevent chafing—a most detrimental and incurable defect; the horny prominence of elbow to be of medium size. The boss to be sound, free from wounds and morbid growths, and well developed. The flexor tendons to be fine and regular in contour throughout their length, as trotting camels are liable to strain and thickening of these tendons from severe and long-continued work. The pad of foot to be well developed, hard and sound, and free from fissures. The toe nails (often a cause of lameness) to be of normal growth. The hump to be of moderate size. This, however, much depends upon the breed of the animal. In the Aden and riding camel it is generally small, in the baggage camel large and covered with long and coarse hair. Allowing for this difference, it is a fair indication of the condition of the camel. It should be quite sound, as injuries and bruises of the hump are most intractable to deal with, from its low vitality and organisation. The back and loins to be well covered with flesh, and to be free from scars and sores. To be muscular about the quarters and thighs, and to be free from puffiness of the hock and other joints, to sit level when made to lie down, and to perform this latter motion, together with rising, without stiffness or difficulty. To be easily guided, well trained, and to walk and trot without impediment, and without crossing of the hind legs, which denotes weakness. There to be no indications whatever of any skin affection.

The price in Egypt varied between £9 and £15; as much as £20 to £25 must be given for the better class camel. When purchasing for the Egyptian Artillery in 1883, these amounts were reached in several instances. Female camels are usually rejected.

Diseases and Injuries.—Saddle galls formed the large majority of cases; at least 7-10ths were of this class, and were the cause of infinite trouble and annoyance; bony eminences being numerous in the camel, and being covered in most cases only by the skin, will in great measure account for the liability to rub and gall. Defective and ill-fitting saddles, heavy loads sustained for long periods, with long marches, considerably added to the list. It is no exaggeration to say that 8 per cent. of the camels purchased were suffering from saddle injuries at the time of their arrival at Assouan, and had to be admitted for treatment into the sick depot before being issued as serviceable. Some 3,000 animals passed through this station while I remained there, so that the sick lines were always well stocked with these cases. A convoy of Aden camels, which marched from Kosseir to Assouan, occupying 16 days *en route*, were only once off-

saddled, I was given to understand. This careless treatment cannot be too highly condemned, as many were placed *hor de combat* for several weeks in consequence. Animals in low condition suffered the most.

Method of treatment.—Exit to pus by depending orifice, removal of all dead and dying tissues, cleansing and syringing with carbolic lotion, and plugging the wound with pieces of tow dipped in the solution, to be removed daily until it assumed a healthy appearance. In indolent and foul sores, spirits of turpentine was applied to stimulate the healing process, and with beneficial results; the first action being achieved, it was diluted with oil, and continued with success. In other cases scraping the internal surface of the wound was found to act advantageously, in others setons were employed. Where the bone was injured, and the ends of the transverse processes of the dorsal vertebrae are especially liable to be so, recovery was greatly retarded, as much as from five to eight weeks being required before such cases could be discharged. Sacking for covering the wounds was found very useful in protecting them from flies and dust and other foreign matter. Every camel should be supplied with a saddle-cloth of sacking, which can be used for the above purpose, as well as being employed as a "roll" to protect the back from the pressure of the saddle, wherever liable to rub or gall.

Skin diseases fortunately did not exist to any great extent. I was always able to keep a certain control over them, which, considering the number of animals, was rather remarkable. I recognise two forms—contagious and non-contagious; and although, in the former, being unable to prove the existence of acari, still, from the difficulty experienced in eradicating the disease, I have not the slightest doubt but that they were present. The non-contagious is a comparatively simple disease, due probably to errors of diet and other influences working unfavourably upon the system.

Treatment of contagious form.—Isolation, clipping the hair if necessary, and cleansing with soap and water, and dressing afterwards with a solution of McDougall's dip; it being found that the watery solution evaporated quickly, besides inducing a dryness and chapping of the skin, "gee," native butter, was used instead as a diluent with more marked success, although the advantages of the McDougall compound, from its prepared condition, and the handy way in which it is packed, rendering its transport and employment more practicable and expeditious, are considerable. I cannot but think that the ordinary pharmaceutical preparation in general use for skin affections would have been more efficacious. Three and four dressings were often necessary; care should be taken that the animals do not get chilled after being dressed.

Debility, often associated with more or less severe diarrhoea, caused some trouble, chiefly noticed amongst the younger camels, and those which had marched long distances, *e.g.*, amongst a convoy which marched from Cairo to Assouan, a distance of about 600 miles in something under one month, which gives a daily average of more than 20 miles, there were several cases; these animals were expected to be fit for issue and work immediately after arrival. Treatment.—Rest, change of diet, and quiet exercise, with a covering at night. A condition would have been of great value, and should be supplied in quantity to depots for use in this particular condition. Grazing, if properly carried out, would prove very beneficial in these cases.

Catarrh, accompanied by laryngitis, was somewhat prevalent for a time, caused, no doubt, by the coldness of the nights, and the want of protection (coverings) from the wind. Only temporary inconvenience resulted from this ailment, however, as few animals succumbed; in a colder climate one might expect this disease to spread and to cause considerable havoc, the extensive

laryngeal and pharyngeal mucous surfaces in the camel rendering it particularly susceptible to throat and subsequent lung affections. Treatment.—The application, with friction, of a stimulating liniment to the throat, with soft food and covering at night; saddle-cloths, already noticed, would here prove of further advantage.

Pneumonia.—A few cases as a result of the above, and also from the presence of hydatids, which, in several post-mortems made, I found to be numerous.

Phthisis, in the acute form, was also met with; it exists, I believe, to an extent more than is generally supposed, for I have been given to understand that an annual death rate of 30 per cent. is allowed for, and reckoned upon, amongst the camels belonging to the Egyptian Government Domain lands, the chief causes of this heavy mortality being due to hydatids in the lungs and phthisis (M. Piot, Veterinary Surgeon to the Domain).

Wounds and injuries of all descriptions, including gun-shot wounds, were encountered, and subjected to ordinary methods of treatment. Here I may mention that particular attention should be paid to the "boss" in purchasing; for, if injured, a considerable period elapses before again becoming sound, as each time the animal lies down the wound is subjected to much pressure, which is harmful, as well as the liability to the entrance of foreign matters. Surface injuries quickly undergo repair in a dry climate like the Soudan.

Chafing of the elbow and side, either from the turning in of the point of the elbow, or over-development of the horny pad covering it, is often the cause of great annoyance, the more so, as it is practically incurable.

In one case of chafe which came under my notice, the abscess which formed in the seat of injury, penetrated and opened into the cavity of the thorax; in this manner setting up traumatic pleurisy, which caused the death of the animal.

Lameness, infrequent.—Cases of foot-soreness from long and continued marching were occasionally admitted into the infirmary. Owing to the nature of the ground this was comparatively rare, rocky and rough travelling being the exception, not the rule. Treatment—rest, cleansing, and the application of an emollient, the patient being kept in the recumbent position as much as possible.

Abnormal growth of toe-nails sometimes induces what at first might appear to be a somewhat obscure form of lameness, the cause not being suspected. The treatment here would be obvious.

Canker of ear, rare.—Usual symptoms and treatment. Crupper galls, often severe, caused by the crupper generally in use by the natives, but dispensed with in the Service; being substituted for by a breastplate; there being a greater tendency for the load to slip backward than forward.

Tetanus supervened upon many of the saddle injuries; it occurred more particularly at Gubat, after the hardship and privation of the desert march. As circumstances prevented the removal of the saddles for some seven or eight days, the wounds could not receive the attention they so much needed, and became enormous gaping sores, exposing an extensive and very sensitive surface to the air, from which traumatic tetanus could only be expected to result, the marvel being that more did not succumb to it; in several instances, however, it was the sequel of slighter wounds. This can be explained by the great tendency of injuries in general to take on this action in hot climates. Treatment of little or no avail. Hypodermic injections of morphia were tried without success, even in the earlier stages of the disease.

Pyæmia, equally fatal, carried off many camels, or caused them to be shot on the road, unable to proceed.

An eruptive febrile disease, called small-pox by the natives, was met with in an isolated form, showing no tendency to spread, and not necessarily fatal.

Exhaustion.—Several and varied influences combined to cause the heavy mortality witnessed in the desert march from Korti to Gubat, but the chief was forced and long-continued marching. The 1st Column which left for the Gakdul Wells, averaged over 30 miles a day; the 2nd Column whilst on the march, about 25 miles per diem. Overpacing whilst heavily laden, with insufficiency of food and water; the allowance of grain per camel between Gakdul and Gubat was only 11 lb., and the journey occupied six days (less than 2 lb. per day), while no water could be given during the same period. It is true that grass was comparatively abundant, but no time could be allowed for grazing to be carried out, and the number of the camels composing the column was quite sufficient to prohibit it in an enemy's country; and although everything was done in the way of collecting the coarse grass and portions of bush, still camels do not take kindly to this manner of feeding, it being their nature to pick and choose when turned out to graze. The march being completed, there was no grain procurable at Gubat, most of the camels having to do the return journey to Gakdul with only a few loads of green dhourra stalks and what grass could be collected to subsist upon. The greater number of camels, after performing the first march from Korti to Gakdul and back (192 miles in six days), were again required to set out, after only two days' rest, for Gubat (172 miles), and this with an altogether inadequate allowance of grain and water. The great mortality which resulted can hardly be a matter for wonder.

Forage allowance at Assouan.—Grain (dhourra or beans), 10 lb.; tibben (chopped straw), 15 lb. for the baggage and 10 lb. for the riding camels. At Wady Halfa, 11 lb. grain and 11 lb. tibben all round. On the march up country, 10 lb. grain; practically no tibben. Korti, grain, 5 lb.; green dhourra stalks, as much as could be collected; no regulated allowance.

Between Korti and Gubat, the allowance dwindled down to 2 lb. of grain per diem in many instances; some corps, better supplied, had as much as 5 lb. for the first few days of the march. The scarcity of grain was due to the difficulty of its transport up country. A composition feeding cake of portable weight and shape, like linseed cake, would be invaluable under such circumstances. It is just possible, however, that the animals would require educating to this kind of food, and this would be an objection to its use. Green forage was supplied when practicable to the depots; this is a necessary and important adjunct. It was the custom to feed twice daily, morning and evening, the largest portion being reserved for the night. Feeding on grain alone, as they were obliged to do for some part of the time, is very detrimental, interfering with rumination and causing indigestion and diarrhoea; like other animals they require a certain amount of bulky food to remain in health. Beans should always be crushed or split, and a like process would be of service in the case of dhourra. Barley had to be given when there was a scarcity of the other two cereals; it does not appear to agree, however, with the constitution of the camel; time is necessary to allow them to feed and ruminate. A very good, rough division of the day is—eight hours for work, eight to feed and to ruminate, and eight to sleep and rest. How seldom could one put this excellent rule into practice!

Grazing, where practicable, is very beneficial, giving the camels exercise whilst collecting their food. It is said that they are not good selectors, often eating plants known to be injurious. In my small experience I did not discover this.

Watering.—It is the custom to look upon this so-called "ship of the desert" as somewhat of a mystery,

on account of its ability to endure the privation of thirst for several days, and it is treated accordingly by many, who act upon the principle that because a camel can live for four, five, six or even more days without water, that you may allow it to do so, or at least stint it, when this commodity is abundant. I consider it is only necessary for their comfort to water every other day when on dry food and the weather not too hot; when on green food less often will suffice. It is a good plan to leave this point to the discretion of the animal itself, although where large numbers have to be dealt with some system must be adopted. I found that nearly all drank eagerly when watered every alternate day; there is no doubt, however, that camels can be, and are, trained in this particular. The inhabitant of the desert is more valuable, therefore, where there is scarcity, than its fellow of the cultivated district, where water is abundant and always get-at-able. The three sets of compartments attached to the rumen, and supposed to be the natural reservoir upon which the camel can draw, having previously distended them with the fluid, contain, on post-mortem examination, portions of the food mixed up with it. This may be owing to the relaxation of the muscular bands after death, with which they are abundantly supplied; the opening and shutting of these apertures can hardly be under the control of the will.

Exercise is very necessary, and should be carried out daily at the depots for at least two or three hours; it is advisable that it be got through in the early morning, to induce a more vigorous circulation of the blood after the cold of the night.

Marches.—The ordinary pace of a loaded "baggage" is put down at 2½ miles per hour, and the working day 8 hours, i.e., 8 hours under the load, which with a convoy would mean 6½ hours' clear marching, to allow for the time occupied in loading up; this would give a distance traversed of about 16 miles, which is quite far enough, not to over-tax the capabilities of the animal. Owing to pressure of time and other circumstances, this rational treatment could seldom be indulged in. Ten to twelve hours doing from 20 to 25 miles, was the more usual routine of work. The riding camel, although not necessarily a faster walker than the baggage one, can be used at the trot for several hours consecutively without apparent distress, doing from 6 to 8 miles per hour.

Although of greater value in despatch and other services requiring celerity, I cannot admit that they have any advantage over the baggage camel in ordinary desert warfare, where the fighting force must necessarily be attended by a large convoy carrying supplies; here the pace is regulated by the slowest, the "trotter" having to keep with the "baggage," and owing to the greater weight-bearing power of the latter, I consider they could be employed to better advantage, and more economically, as mixed fighting and baggage animals; thus obviating a separation of the two, which would allow of a reduction in the total number, as well as a reduction in the matter of forage and the corresponding transport required for its carriage. Trotting camels could always be attached to every column to carry out their especial service. This mixed system is still in vogue in the French Army in Algeria, and is, I believe, found to answer admirably.

Rest should always be allowed, in fact insisted on, after every march of any distance: nothing wears the animals out sooner than being continually on the march. Some go so far as to say that the days of work and rest should be equally divided.

Drivers.—At least one to every three camels, otherwise they cannot be properly looked after and cared for, or the loads properly put on and adjusted on the march. In the late campaign, it sometimes happened that there were five, and often six animals to one driver. The

Somali and the Aden Boys are superior in this particular to the ordinary Egyptian, for although smaller in stature and not so strong, they take a much greater interest in their charges, are more active, and being "clanish" they are always ready to help one another in difficulties. In the desert march they behaved admirably, and showed a good example to Egyptian soldiers and others employed as drivers.

Loads.—From 300 to 400lb, according to the size and strength of the camel, is considered an ordinary load: it should not exceed 300lb where long and continued marching has to be gone through (exclusive of saddle). No absolute and uniform rule can be laid down, as much must be left to the discretion of those in charge. Gross, and not nett weight, should be the one adopted when stores were being issued for transport: the Commissariat Department are only too prone to consider the nett weight, as that alone concerns them. The Transport Department have to deal, however, with the gross weight, and in this case, where matters are urgent, it is the poor beast that suffers, to its own detriment, for at least 25 per cent. has to be added to the nett amount, to include boxes and other cases, often tin-lined, in addition. The boxes for protecting stores should neither be too large nor too weighty (as were the large-sized biscuit cases recently in use); otherwise they are cumbersome to load, and by their greater aptitude to shift, and take up the motion imparted by the animal, are more liable to gall the back and cause further evidence of distress; the great weight and consequent pressure of a heavy load is sufficient in itself to impede and arrest the circulation in the skin, and thus give rise to those injuries which interfere, to no small degree, with the mobility of an army.

Saddles.—A subject offering many points for consideration. The service-pattern riding saddles were principally of two designs, the models being borrowed from those in use at the time in the Egyptian Camel Corps. Modifications and improvements could be made in them, with advantage, though on the whole they answered the purpose required of them. The lashings and woodwork were not always of the best, and often gave way. This was hardly to be wondered at, as they were made by contract and ordered at short notice. With ordinary attention from the rider, no camel, issued sound, should have developed sores or galls, unless under exceptional circumstances of marching or of condition.

Baggage saddles.—Those made specially for the Expedition were mainly of one pattern and of one size, others brought with the camels were of various sizes and shapes. Those from the district around Esneh were superior to all others, being stronger, more stable, and hence more suited to carrying heavy loads. The service-pattern saddle had several defects, the chief being want of strength in the trees and being of one size they were unsuited to the smaller camels, and caused much trouble in altering. The stuffing being of coarse straw, soon wore through the non-durable lining, causing chafes and galls. Fitting on the back as an acute angle Λ , they rested for the main part at the rear, on the extremities of the transverse processes of the dorsal vertebra; a part most liable to injury, especially when an animal is in low condition. The spine bore very little of the weight, and the hump was over-crushed and bruised, not only by the load, but also by the make of the saddle, and the unyielding portion of the trees. The hide lashings often gave way, allowing the key which binds the two halves of the tree together, to come right down upon the wither, and cause by attrition most dreadful sores, very difficult to cure. At a Board on these saddles, of which I was a member, it was suggested that the hide lashings should be substituted by rope; that there should be greater strength and stability of tree, which should also be more open; that the pads be made of two or three different sizes, that the hinder one be lined

with leather to protect the loin, and that these two rear pads, being made into one, be joined at the top, so as to allow the spine behind the hump to take its share of the weight. Breast-plates of soft rope or other material should always be issued with the saddles. The Dongolese pattern saddle is very light, and only suitable for a small load; it is most indifferently padded, and many of the galls must be laid at its door.

The Remount and Sick Depots at Assouan and Wady Halfa were combined, each under one Commissariat Officer. I would advocate a separation, allowing the Sick Depot to be under the control of the Veterinary Surgeon, who should alone be responsible for its working: in fact, to be managed as a military hospital, apart from the interference of the non-professional element. A proper staff should be given him to enable this to be carried out. The disagreements which often arise under the combined system would then be done away with; for the least impartial judge must admit that a professional man must be the best exponent of his own particular calling.

During the five weeks I remained at Assouan, some 3000 camels passed through the remount, and some 300 through the Sick Depot. At Halfa over 200 were admitted for treatment during a period of three weeks.

The Staff of Assistants was inadequate, and they were quite uneducated in the commonest matters of treatment. As camels require no shoeing, little or no thought was paid to the subject of farriers and shoeing-smiths prior to the arrival of corps at Assouan. The Camel Corps had made no provision for men to act as dressers, or to attend animals when on the sick list. At my suggestion, the Commissariat Officers of both the Heavy and Light Divisions sent down one man per troop or section (45 camels), to the Sick Depot daily to learn the simple methods of attending and dressing wound cases; many of these men had previously been shoeing-smiths, but when volunteers were called for in their respective regiments, rather than be left out they gave up their "Shoe" to revert to privates. As an inducement to accept this duty, an extra 6d. per diem was promised them, which they would be entitled to after the campaign would be over. Two of the Transport Companies which came from England were provided with farriers and shoeing-smiths as part of their ordinary establishment; when requiring further help men, without any special training, were detailed to assist them, but often remained in independent charge, owing to the splitting up of the companies along the Line of Communication. Owing to the scarcity of qualified assistants, I had attached to me for duty a serjeant of the Gordon Highlanders to act as farrier, and a private of the 15th Hussars to act as dresser—these men to permanently remain with me wherever I might be. On arrival at Korti, the latter was recalled to his regiment, and being under orders to proceed to Gakdul, I was unable to have this very summary proceeding enquired into, or even get a substitute before leaving. Only a special corps of trained men will ever meet our requirements adequately; without a competent staff, the Veterinary Surgeon's time is taken up with teaching the so-called assistants, and other minor matters of detail, when it might be otherwise employed much more profitably.

Medicines.—In addition to the field chests in use by the Veterinary Surgeon, each sub-division of a corps was given a small box containing medicines and necessities sufficient to meet ordinary requirements. These unit chests were devised by Mr. Burt, Principal Veterinary Surgeon of the Nile Expedition: a very fortunate and wise provision, where veterinary surgeons were so few, the animals so numerous and scattered, and the distances so great. By this system, each part or unit of a corps had the means of attending to whatever sick cases there might be amongst its own camels—chiefly saddle galls—and no excuse could be made for neglecting

them. One, and sometimes two boxes, were supplied to each section of transport (167 animals), and one to every two sections of the Camel Corps (90 animals), and to other corps in the same proportion. Each chest had written directions for the employment of the ingredients it contained. I think this system has everything to commend it, provided that competent hands guard the expenditure, and especially having regard to the length of the line, when it may be impossible to attach veterinary surgeons to separate corps.

Branding.—It was the custom to brand a broad arrow on the right side, and numbers progressively on the left side of neck; nicety of manipulation is required: otherwise, if branded too deeply, the figures become obliterated by sloughing of tissue, and if too lightly done, it soon wears out and becomes undistinguishable. The numbers on the irons should be cut clear and not stamped on the block, otherwise they blurr. A wooden handle, of sufficient length, would greatly convenience the brander, and enable the work to be more thoroughly carried out.

Typhus Bovine.—Rinderpest developed itself amongst cattle arriving at Assouan, brought direct from Odessa for the use of the Army, although passed free, after the usual 24 hours quarantine at Alexandria. Twenty-one deaths occurred in a cargo of 50 between Assiout and Assouan, and it was found by me, on examination, that the remainder had contracted the disease also in a great or less degree. Many post-mortems were made, and the characteristic lesions found in each case. A report was sent by the Principal Veterinary Surgeon to Cairo, explaining the gravity of the outbreak, and a strong private letter by myself to Dr. Sandwith, the then Sub-Director of the Sanitary Board of Egypt, and with whom I had worked on this same subject last year, urging upon him the necessity of closing all Egyptian ports to Russian cattle, owing to the great danger to the country by the continued importation. The opportunity was not thrown away, and I am glad to be able to say that their entrance is now prohibited. A second cargo also lost several animals *en route*; local supplies of cattle were then utilised to meet the demands of the Army, and the risk of bringing infected animals through such a long stretch of territory done away with.

E. E. BENNETT, Veterinary Surgeon,
Army Veterinary Department.

London, June 12, 1883.

(To be continued.)

LINCOLNSHIRE VETERINARY MEDICAL ASSOCIATION.

The summer meeting was held at the Angel Hotel, Peterboro', on Friday, June 16th. The chair was taken by the President, Mr. W. W. Grasby, of Daventry. Other members present were: Messrs. T. Holmes, Bourne; A. Lennox, Crowland; T. B. Bindloss, Long Sutton; F. L. Gooch, Stamford; C. Hartley, junr., Lincoln; T. Hicks, Sleaford; R. W. Knowles, Wisbech; G. Lockwood, J. Mackinder, H. Westgate, Peterboro'; H. H. Nicolls, Oundle; E. W. Parkes, Wellingboro'; J. H. Coles, Whittlesea; T. A. Rudkin, Grantham; W. K. Townsend, Market Deeping; C. W. Townsend, Long Stanton, Hon. Sec.

Visitors: Messrs. A. Over, Rugby; F. W. Medlock, Board of Agriculture.

Previous to the meeting the members were hospitably entertained to luncheon by special invitation of the President. The loyal toasts having been duly honoured, Mr. F. L. Gooch proposed the health of the President, and in the course of his remarks said he was sure Mr. Grasby would add lustre to that position he now occupied. He was sure he was expressing the feelings of all

present when he told the President how thankful they all were to him for his present generosity. He himself did not know if the lunch had brought them together, but it certainly was one of the best attended meetings he could remember—and he was one of the oldest members of the Society. At one time they had thought of dropping their meetings, but he now hoped that the present meeting was going to be the turning point, and that all the members would support both the President and the Secretary by regular attendance at the meetings. He hoped they would have some good papers and discussions, by which, with regular attendance the Society would continue to flourish; by so doing they would make Mr. Grasby's presidential year a success which he fully deserved. (Applause).

The PRESIDENT, in returning thanks for the kind remarks made by Mr. Gooch, said it was a great pleasure for him to be in the position he was that day. It was true he took the position with some amount of diffidence, as the meetings had been so poorly attended during recent years. He knew it was often difficult for single-handed practitioners to get away, but there could be no excuse for continued absence year after year. The result of their associating must be for their general good; he himself had never yet attended one of these meetings without having added something to his present knowledge, and he did hope each member would support him by attending as regularly as possible.

The minutes of the last meeting were passed, on the motion of Mr. Knowles, seconded by Mr. Holmes.

The HON. SEC. announced that he had received letters and telegrams regretting inability to attend from Messrs. H. C. Taylor, W. A. Allott, W. W. Lang, R. W. Clarke, C. Hartley, senr., A. Johns, T. J. Keall, S. G. Masterman, J. Marshall, W. Hoole.

The HON. SEC. reported the death of one of the oldest members, Mr. J. W. Gresswell, of Peterborough, since the last meeting. He did not hear of his death until the morning of the funeral, but in the meantime his successor, Mr. Lockwood, had kindly undertaken to represent the Association there, and to send a wreath on their behalf. He had written Mrs. Gresswell a letter of condolence, and had received an acknowledgment.

Mr. J. MACKINDER, in proposing a vote of condolence with Mrs. Gresswell, said he was now perhaps the oldest member, he and Mr. Gresswell having attended the meeting at Lincoln at which the Association was instituted. He had known him for 42 years, and he only had a disagreement with him on one occasion, when he (Mr. Mackinder) had to admit he was in the wrong. They had been great friends, and he felt his death very much.

Mr. GEO. LOCKWOOD seconded, and said he was sure they would all miss Mr. Gresswell's genial presence at their meetings, at which he had been a most regular attendant, sparing himself no trouble to be present. If other members only followed his example, they would have better meetings. The resolution was carried in silence, all standing.

The SECRETARY announced he had received a letter of resignation from Mr. Lang of Brocklesby, and he had already written Mr. Lang asking him if he could possibly continue as a member.

Mr. Lang had explained that he was now at Brocklesby, which had a very poor train service, so that it was very inconvenient for him to be present at the meetings, but on the suggestion of the President, Mr. Hicks undertook to ask Mr. Lang personally to reconsider his decision to give up his membership, and to invite him to the Lincoln meeting in October.

The HON. SEC. said that Mrs. Masterman wrote to say that her husband was away, but she hoped that he would soon be completely recovered from his hunting accident.

A member was reported for being four months in arrear with his subscription, but instead of striking him automatically off the list of members in accordance with the bye-laws, it was decided that his attention should be called to his default.

The balance sheet of the Royal Victoria Benevolent Fund, to which the Association subscribes 2 guineas annually, was laid before the meeting, the Secretary stating that through his inability to be present at the last meeting he had upon his own responsibility sent 2 guineas towards the above fund, as if he had waited until the present meeting the subscription would have been much overdue.

On the motion of Mr. Gooch, seconded by Mr. Holmes, it was decided not to accept the invitation to the Sanitary Congress at Belfast, and the Public Health Conference at Dublin, owing to the distance: the proposer remarking, too, that there were opposing interests in the two Societies.

Mr. F. W. MEDLOCK, of Peterborough, an Inspector of the Board of Agriculture, was proposed as member by Mr. H. Westgate, seconded by Mr. Mackinder.

Mr. COMBERFORD, of Caxton, Cambs., by Mr. C. W. Townsend, seconded by Mr. E. W. Parks.

PRESIDENTIAL ADDRESS.

Mr. W. W. GRASBY, Daventry.

Gentlemen,—I appreciate the compliment in your electing me as President. As a native of Lincolnshire, it is only natural that I have taken a great interest in the welfare of this Association, and although comparatively a junior member, I have always read the proceedings of your meetings and watched progress. My first acquaintance with members of our profession was of men who held office at different times in this Association, men, too, who were held in high esteem by their clients, and whose names were household words in this county.

As a profession, I venture to assert that we deserve all the credit we get, but it is equally true we deserve more of the British Public's recognition than we obtain. A veterinary surgeon, more particularly a country practitioner is, if I may use the term, a whole-time man; few people outside our own profession can have but a scant idea of the really physical labour than is entailed in our every day life, and to no one is it more necessary than to us, that we should be possessed of every mental and physical faculty. There is no old age pension when we are past the hard active work, and fortunate is he amongst us who saves enough on which he may retire from his labours. A lawyer has his head and pocket only to consider, but we must use head, heart, and pocket too. Every labourer is worthy of his hire, but in not a few of our cases the fees obtainable are much lower than their real worth. Ours is a profession that can never be put on a purely commercial basis; for some of our drudgery we must be content with, and rely on, gratitude.

Once we leave our College, we many of us of necessity lead isolated lives, rarely seeing a colleague, and unfortunately, perhaps, some of us may get into a groove and so desire to see less of our brother practitioners. Hence the value of being a member of a Veterinary Medical Society cannot be denied; singly, or even in cliques, men and their ideas fall apart, but undoubtedly unity at least promotes good fellowship, ensures interchange of ideas, and so adds dignity to our profession, and to us as individuals.

As a rule we do not appreciate quite enough the importance of continuous education in our professional life, we must endeavour to be up to date, and keep in touch with each advance in our profession, and contact with men who are doing good pioneer work is a surer means of obtaining that end, and easier than a course of

reading, however thorough. There are many of us who would gladly appreciate a post-graduate course if we could afford to leave our practice, and as a remedy it should be as much as possible brought to us by the Veterinary Medical Society to which we belong, and you will, I hope, pardon my saying that the greatest compliment you can pay the officers of this Association is your regular attendance at each meeting as a practical proof of your appreciation of their efforts to provide interesting subjects for your consideration.

Debate should be encouraged, particularly among junior members. They may rest well assured the seniors are not feeling bored, but taking keen interest in the views put before them. We must all acknowledge the very great advantage in his College education of a graduate of recent years over that received twenty years ago.

I have the very happiest recollection of the great help I have always received when it has been necessary to ask advice over a troublesome case at any meeting of a Society such as ours, and always found any member willing to give me a patient hearing before offering his opinion, and have invariably returned home richer in knowledge and cheered by help so willingly given.

It is not always an easy matter to arrange an attractive programme for each meeting, but a few clinical cases recorded, even though they be of every day occurrence; pathological specimens—always of interest; a short paper productive of discussion, and an occasional demonstration, should be tempting enough to make us grasp the opportunity for half a day spent enjoyably and profitably away from the ordinary routine of our daily life. We must not be content to be practical men only.

Again, too, a Society such as this used properly is surely a specific against any feeling of mistrust and jealousy, a sin of the heart which so readily attacks at times each one of us. We should, then, use every endeavour to place ourselves in a position to render better service to our clients, and the public will be more appreciative of us, particularly those who read and take note of the progress in veterinary medicine and surgery, and this, too, must prove a powerful stimulus against those feelings of self-sufficiency, and those careless habits into which even the best of us find it so easy to relapse.

Unlike the medical profession, we have no general hospital within a few miles to fly to, which is so valuable to their individual members, and to which they can dispatch a difficult medical or surgical case, and at very little inconvenience watch the progress made under the care of a specialist who is provided with every facility by generous donations from a grateful public. With us the practitioner has a constant difficulty in obtaining anything approaching sanitary surroundings even for his patient, and a skilled willing hand to assist is most difficult to obtain within a reasonable time. He is expected to be prepared to battle with any difficult surgical case that may arise at a moment's notice, when not only skill is required but much manual labour.

The modest income of many of us will not admit of our being extravagant in the purchase of medical or surgical appliances which are not very frequently required, and really I can imagine it must be a very happy state of mind for a veterinary surgeon to be in a position to fit up his establishment with every modern requirement.

At the present moment the very unsatisfactory financial position of the Royal College of Veterinary Surgeons cannot fail to appeal to every member of our profession, and I believe that a voluntary subscription from those who feel disposed is the best means of tiding over the difficulty temporarily. For the welfare of the whole profession it is imperative that the stigma of want of funds should be removed at the earliest opportunity,

and looking through the lists of bequests in our daily papers it seems to me so characteristic of the world's neglect of our profession that amongst many large sums given to already well endowed institutions not one thought is ever given to us—the poorest of all professions—and to which a few hundreds even would be of such marked benefit for the welfare of the whole animal world and as a result give pleasure and profit to owners of animals that words cannot adequately describe.

With regard to the politics of the profession I will not weary you, enough has been said in the press lately in election addresses. Of the new Bill I approve. It is absolutely certain those in authority at Red Lion Square cannot look after our interests with due advantage to us without capital, and you will agree we need much better protection from the ravages made by unqualified men. It is strange, but true, that there are men who, well educated but unprincipled, having some knowledge of medicine and surgery, can bring about disastrous results to a good practice. It is most astonishing how the public can be influenced by a clever unprincipled man.

It is the duty of every parent or guardian of the future veterinary student to spare no expense in his education prior to his entering College, for certainly in the future it will be the men with the highest training who will be successful in obtaining the most prominent public appointments appertaining to our profession.

Our efforts in prevention and treatment of disease are certainly more appreciated every year, but there is much more to hope for, particularly in our smaller towns, in which those in charge of its welfare show a total lack of the requirements that are so essential for the proper supervision and inspection of the food of its inhabitants.

In conclusion, gentlemen, I thank you for listening to these remarks. If you will give me your support during my year of office, with the help of our friend and Secretary, Mr. Townsend, to whom we owe a debt of gratitude for his untiring energy, I will do my utmost to make each meeting pleasant and instructive. (Applause.)

Mr. GOOCH proposed a vote of thanks to the President for his address, which he suggested should be recorded in the minutes, containing as it did several matters of interest to the profession.

Mr. HICKS seconded, and the motion was carried with acclamation.

THE NATIONAL.

Tacit approval was given to the amended rules proposed by the Committee of the National Veterinary Association on the motion of Mr. Holmes, seconded by Mr. Westgate.

INSTRUMENTS AND THEIR USES.

Mr. F. L. GOOCH then exhibited a very interesting set of surgical instruments, and in a preface explaining their uses, said:—

Mr. President and Gentlemen,—I must first of all apologise to you for the subject before you for discussion. When I proposed you as President, sir, I did not agree to give a paper, and I was very glad when you informed me you had secured a paper for the Peterboro' meeting, and I am only sorry the gentleman found himself unable to give us a paper on "Contagious Abortion in Cattle." Knowing the gentleman as I do I feel that he would have done justice to the subject, and aroused a very good discussion as the subject would be most interesting to provincial practitioners, and it was only owing to the great persuasive powers of your President that I consented to give a few notes on some every-day instruments, hoping for the contribution of other men's experience by way of discussion.

I do not intend to bring to your notice anything new,

but I do hope to explain some alterations, which I consider improvements, in some of our every day instruments. Before dealing with any one particular instrument I should like to preface my remarks.

The Keeping of Instruments.

I consider that every practitioner should keep his instruments, no matter how few he might possess or how great the number, in a clean, aseptic, and bright condition. I have sometimes been disgusted at the condition of instruments in some of our public institutions, as well as in some practitioners' surgeries. This is not only detrimental to the life of the instruments but in the eyes of the public detrimental to the institution or to the private practitioner, as well as frequently a source of danger to our patients. I, myself, have been asked to attend cases in which an operation performed by an empiric has been the cause of blood poisoning, and also in one case in particular in which a disease was spread to twenty-one animals by inoculation through an infected instrument.

When in the surgery they should be arranged as far as possible so that one instrument may be obtainable without many others, and also, if possible, in glass cases, so that one's clients may be able to see them if they should visit your surgery. It is surprising what opinion your clients may form of you by the condition of your surgery—more particularly as to its cleanliness.

There are numerous instruments manufactured by the instrument makers that are not worth the metal they are made of; they are only fit to adorn an instrument shop and are only wasting room in a surgery. The other evening I was in the company of one of our professors who told me that a surgeon in the first rank of his profession told him that he wished that a practical surgeon would turn instrument manufacturer.

That is just what we want in the veterinary profession. Myself, I have been very fortunately situated. I have not only a mechanical turn of mind myself, but I have a father who can make exactly what he requires, and many a time we have come home from a difficult operation saying we wanted an instrument of such a nature, and he has immediately set to work and forged an instrument to meet the case the next time it may occur. Practically that has been the way in which nearly all the instruments that I venture to speak on this afternoon have been thought out and made.

Many of our instruments of course, on account of the size and strength of our patients, have to be made very heavy and unwieldy, but frequently an instrument maker will make them strong and heavy where it is unnecessary, and light and weak where strength is required. This I think I can substantiate in one or two instruments before you.

Choice of Instruments. This more particularly applies to younger members of the profession. It is almost impossible, unless you are a very wealthy man, to purchase all the necessary instruments at once, but I would advise any young man to purchase those instruments he requires most in the district in which he intends to practice, and above all, to buy the best instruments. Cheap instruments are always dear in the long run. It is surprising how some practitioners get through with very little expenditure on instruments, and I have been called upon to perform operations in a brother practitioner's infirmary, when I have required the most commonplace instrument, and it has not been forthcoming or if it was, it was of such a primitive character that it was almost impossible to apply it to recent surgery.

Mr. Gooch then displayed his instruments one by one, fully explaining their use. The exhibits included a twitch, a dog muzzle, firing irons, a wart iron, two sets

of parturition instruments in cases, foot shears, lamb claws, sandcrack instruments, teeth instruments in case and out, a tourniquet for docking, shoeing tackle, abscess bistoury, wound sutures, a patent fleam, trocar and canula (abdominal), a mouth gag, a pill deliverer, and balling guns (Stewart's).

The PRESIDENT exhibited various instruments, also a very neat medicine chest which he always took with him in his trap.

Mr. LOCKWOOD wished to thank Mr. Gooch for the excellent display and description of the various instruments, remarking that with such a collection one needed no instrument maker. He also expressed his approval with the remarks made by the essayist with regard to the advantage claimed for his tooth instruments over those of some now in regular use.

Mr. MACKINDER, in thanking Mr. Gooch for his excellent display, said that the essayist had pleased their eyes as well as their ears. There were, he added, no end of instruments before them, and to possess them all one must be almost a Rothschild. He thought Mr. Gooch had made a mistake in not being an instrument maker.

Mr. TOWNSEND said he must first of all thank Mr. Gooch for so kindly coming there that afternoon and filling up a gap which at one time seemed evident. He must also, like the President, thank the members for turning up so well at this meeting, he did hope that the present meeting was only to be the first of a series of successful meetings, and that they would have many meetings in the future equally successful. The Society had, as the members were no doubt aware, certain in-

struments, but he was sorry to say they could not at present give such an excellent display as they had before them at the present time.

Mr. OVER, as an old friend of the President, and as a visitor that afternoon, said he could not let the present opportunity pass without thanking both the President and the members for the enjoyable time spent with them that day. To the Essayist, also, he wished to add his thanks, for he thought the display and general description of the various instruments was excellent.

Mr. LOCKWOOD, on behalf of the members, had much pleasure in proposing a very hearty vote of thanks to Mr. Gooch for his kindness in coming there that day.

Mr. GOOCH said that both he and his father had always been greatly interested in surgical instruments and it had been a great pleasure to him to come there that day. He should like to add that any of the instruments now before them were at the disposal of the Society,

Mr. RUDKIN exhibited a cystic calculi (*in situ*) obtained from a Pomeranian bitch, he showed it more because of its large size, as to him it appeared to more than half fill the interior of the bladder itself.

A very successful meeting closed with a hearty vote of thanks to the President, on the motion of Mr. Hicks, seconded by Mr. Rudkin, who attributed the successful gathering partly to the personality of Mr. Grasby, and hoped the Society would have many such meetings in the future.

C. W. TOWNSEND, Hon. Sec.

Department of Agriculture and Technical Instruction for Ireland, (Veterinary Branch), Dublin, June 26, 1911

NOTE.—The figures for the Current Year are approximate only.

* As Diseased or Exposed to Infection

Personal.

Mr. W. FREEMAN BARRETT, M.E.C.V.S., Barrister-at-Law, was commanded to attend the Coronation Service at Westminster Abbey as representing the veterinary profession; and was therefore present at the ceremony on behalf of our Body Corporate. All veterinary surgeons will share our pleasure at this Royal recognition of the profession in the person of its official head.

Vet.-Major E. P. J. Barry, F.R.C.V.S., 2nd Life Guards, was called to the Bar on Wednesday, June 28th.

The Duke of Connaught, as a Bench of Gray's Inn, made a special point of being present in hall on Wednesday night, to congratulate Major Barry, 2nd Life Guards, on his call to the Bar, at that Inn, though a couple of years must yet elapse before—the completion of two decades of service in the Army—he lays down the sword to assume the toga. Major Barry, who is of Irish nationality, saw service in the Tirah Campaign of 1897-98, for which he received a medal with two clasps, and was on the Special Commission sent out to South Africa in 1902 to examine into the question of remount supply. He has served with the "2nd Life" for twelve years, and for some time past has also been on the Executive Staff at the Royal Naval and Military Tournament as veterinary expert.—*Daily Telegraph.*

Mr. AINSWORTH WILSON, F.R.C.V.S., of Witham, Essex, was appointed Professor of Surgery and Obstetrics, and **Mr. J. B. BUXTON,** of Barnet, was appointed Professor of Surgery and Dietetics, at a special meeting of the Board of the Royal (Dick) Veterinary College, Edinburgh, on Wednesday last.

ARMY VETERINARY SERVICE.

Extract from *London Gazette*,
WAR OFFICE, WHITEHALL, June 23.

TERRITORIAL FORCE. ARMY VETERINARY CORPS.
William Hepburn to be Lieut. Dated May 10.

Maj.-Gen. R. Pringle, C.B., D.S.O., was the representative of the Veterinary Division of the War Office Staff in the Coronation procession.

THE LIMITS OF DIAGNOSIS.

"Yet some there were, among the sounder few
Of those who less presum'd, and better knew."

Sir,

I must thank Mr. Mayall for his criticism of my article on the above subject.

There are a few points however, which require some explanation on my part, as evidently Mr. Mayall has misunderstood the substance of what I intended to convey.

1st. I did not advise that the practitioner should discuss the pros and cons of a case with his client, or disclose frankly all his fallibilities. What I meant to convey was that it would be an advantage in veterinary practice if clients were better acquainted with the limits of diagnosis, and less inclined to believe in the infallibility of some practitioners. Then they would not expect so much from ordinary mortals and would allow for the possibility of errors.

A medical man is not expected to give a dogmatic opinion at his first attendance on a case, he is allowed ample time, and a careful and prolonged examination is appreciated by the patient and his friends. But in consequence of the tendency which some veterinary surgeons have to give dogmatic opinions after a trivial examination of a case, it has become the custom to expect a rapidly formed opinion, and to ascribe the power of giving such to special skill.

And as I have already remarked, the efforts of the man who devotes special care and attention to diagnosis are not appreciated by the public, in fact he is often described as "not practical" by some, and ignorant by others.

2nd. With reference to the consignment of the body to the knacker, what I meant to convey was that cases in

which a dogmatic opinion as to diagnosis has been given, may die, but no trouble is taken by the practitioner to confirm the diagnosis. In fact the more infallible the practitioner becomes, the less likely he is to trouble himself about autopsies; were he to regularly test the correctness of his diagnosis in this manner, his vaunted skill would soon be appreciated at its correct value.

The owner of the animal takes little interest in a dead body, and unless he is of a litigious disposition, he is not likely to question the practitioner's opinion or skill.

And what an enormous amount of errors in diagnosis are consigned to the care of oblivion, and one might add also, what a lot of valuable pathological material is lost in the same manner.

3rd. With reference to the effect of treatment on the results obtained, perhaps I should have added "by drugs." No doubt attention to hygiene and dietetics proves a valuable assistance to the *vis medicatrix naturae*. I must confess that every year I have less faith in the supposed virtues of many drugs, and more belief in the natural powers of recovery.

That some drugs are valuable no one will deny, but in a large number the therapeutical effects are purely imaginary. A little experience in contract practice gives valuable information in this direction. Here there is no inducement to prescribe drugs, and the results are quite as satisfactory, if not more so, than in ordinary practice, where the supplying of drugs is a *sine qua non*.

A few weeks ago I attended a Shire stallion suffering from influenza, temperature 105.5°. The usual simples were prescribed, viz., small doses of Mag. Sulph. and Pot. Nit. in the food and drinking water. These the animal absolutely refused to touch, so nothing else was ordered. The temperature descended, the appetite was maintained, and a good recovery ensued.

This is not an isolated case, I have come across a large number, and if some of the new anti-pyretics had been prescribed, what a false testimonial I would have given to the drugs.

Consider the number of cases given up as hopeless, that recover when no further treatment by drugs is adopted.

Some time ago I attended a valuable cow suffering from inhalation broncho-pneumonia due to faulty administration of a drench. She appeared hopeless, and drenching was impossible. The owner after some days said he would take no further trouble with the case, as the animal was sure to die. I agreed with him. An old herdsman came along and gave the cow a few raw potatoes, which she ate. From that time forward she improved and made a good recovery.

Query. Had I given drugs the result would have been attributed to their employment; it would be just as reasonable to ascribe the result to the potatoes.

I attended a dog suffering from ulceration of the cornea as a sequel to distemper. The owner was an ophthalmic surgeon, and he wished to carry out the orthodox treatment, but the dog objected so forcibly that I told the owner the treatment would do more harm than good. So a simple boric lotion was prescribed and a good recovery resulted.

This is not an isolated experience, I have often observed that both in horses and dogs affections of the eye have recovered, when all treatment has been left off.

The question of the means adopted and the effects that result is an interesting one. Some years ago I attended a cow the property of a solicitor, for some obscure gastric derangement. On my third visit I found that the cow's tail was adorned with a piece of blue ribbon, and underneath this was a filthy concoction, covering a wound on the under surface of the tail. The attendant informed me that his master had brought a "charmer" or "wise-man" from a village 12 miles away, the previous evening, and that this worthy had cut out a worm from the cow's tail, and applied the charm. Moreover, since the ordeal had been carried out the cow commenced to feed, and was now all right.

An interview with the master corroborated the man's statement, and what was more, he was well pleased with the work of the wise man—far better than with mine. Verily this was "casting anchors of faith into a sea of superstition." Still it is very much on a par with the deep-rooted faith that exists as to the effects of drugs in the minds of horse and stock owners.

En passant, I may say that "worm in the tail" is a very common disease (?) in this district, and accounts for a very varied list of symptoms.

(4) *Re ailments of horses' teeth.* I am of opinion that the unfortunate stomach is more often subjected to the onslaughts of drugs when the teeth are really at fault than *vice versa*. And certainly less harm is done by simply rasping the teeth, even though the skill of the equine dentist is not necessary, than by administering drugs when the teeth really require attention.

I agree with Mr. Mayall that some practitioners overdo the equine dentistry fad, but in the present age of specialists some new fields must be discovered. The teeth are rasped and the horse's appetite returns—means adopted and results gained. From a commercial aspect I think we should pander to the fads of the public and follow the advice of Iago "Put money in thy purse." From a scientific point of view, well, *entre nous*, we must, if we possess any sense of humour, smile secretly at the implicit belief that the public have in the virtues of drugs and in the mysteries of the healing art.

When this belief is shared by the practitioner, and sophomania accompanies the ledger therapist, then indeed we see very little difference between his methods and those of the patent medicine vendor, who pitches his tent in an agricultural show ground and caters for the wants of a gullible public. Both have the same object in view, viz., the making of money, and that both succeed in this laudable desire is unfortunately too well known to those who practise on scientific lines, who admit the limitations of human skill, and are foolish enough to confess ignorance in a calling where dogmatism is the master word to financial success.—Yours etc.,

Cork.

E. WALLIS HOARE.

THE AMENDMENT BILL AND THE OBJECTORS.

Sir,

Mr. Isherwood's comments upon that contemptible "Address to the Members of the House of Commons" in your current issue have voiced the feeling that will be prevalent throughout the profession. But in one respect I think Mr. Isherwood might have gone further. He might well have asked, as I ask now, whether any one of the individuals whose names are appended to the circular has anything to say in defence of it. It was circulated with the object of influencing men unacquainted with veterinary affairs: and as it did not appear in *The Record* till about a month after its issue, we may infer that its signatories were not particularly anxious that it should become known to the profession at all. Now that it is known to us, what have those responsible for it to say for it and for themselves?

Many points in this precious circular invite comment; and we should all be interested to hear any one of the five worthies who signed it speaking on behalf of whatever portion of it appeals to his intelligence as the least indefensible.

But lest they should find a difficulty in deciding this point, and keep silence on that account, I wish to draw their particular attention to one statement in their production, and challenge each and all of them to justify it. In one sense it is the most important portion of the circular, for it is perhaps the most likely of all to have weight with the M.P.'s to influence whom it was advanced. I beg leave to transcribe it in italics—I think it deserves the distinction.

"There is a very strong opposition to the Bill in the form of a Committee consisting of nearly nine hundred members."

Now I should like to ask our five friends what evidence they can give us either that there are really anything like nine hundred members opposed to the Bill, or that they themselves have any faith in the existence of such a phalanx of support? If there are really nine hundred opponents of the Bill, why are they not represented by a majority on the Council? They could have been by this time, and they would have been, if their number had even approached 900. Eight members of Council were elected this year, and the votes they received ranged from 1009 to 646. Nine were elected last year, and their votes were from 973 to 631. These figures

show clearly what 900 voters united against the Bill could have done; and yet at neither of the two elections did this Committee, or ghost of a Committee, dare to put a single candidate in the field. Now I ask these five "Members of Executive Committee" why it is that the opponents of the Bill have made no attempt to influence the Council elections for two years past—and I defy them to find an answer which will not reduce their "Committee consisting of nearly nine hundred members" to *non-existence*.

Is this alleged "Committee" really anything more than the resurrected corpse of some sort of committee which was hurriedly collected (by post-cards in answer to a circular, I believe) to oppose the Bill in its *earliest form* about three and a half years ago, and never justified the assertions then made regarding its numerical strength? Many of its members, no doubt, were men who had been momentarily carried away by the "raging, tearing propaganda" against the Bill which was set on foot early in 1908; and not a few must have speedily withdrawn whatever support they had given to the Committee and its founder. Certainly the election of 1908 revealed no such strength as 900 votes in the Bill's opponents. A year later, in 1909, we all remember that a Committee (probably the same one nominally) ran eight candidates for the Council and failed to get one of them in—and most of us fancied that immediately afterwards the Committee itself died of grief and rage at finding itself so much smaller and weaker than it had thought it was. As an attempt is now being made to give it a semblance of life in order to impress M.P.'s who may well suppose it to be a potent and active body, we have a right to ask those who profess to represent it to give us some evidence of its existence.

A further prospective advantage of such explanation from the five "members of Executive Committee" is that their individual utterances might give us some inkling as to what manner of men they are. Most of us sadly require enlightenment on this point with regard to some of them; though not, I admit, with regard to all. Mr. Hurdall, of course, we all know. As a homeopathist and an antivivisectionist he has greatly contributed to the entertainment of the profession on certain well-remembered occasions in the past; but the mere thought of what would have befallen veterinary science had its votaries accepted Mr. Hurdall's guidance in medicine and pathology is enough for most of us when he presents himself before us as one desirous of shaping or modifying our professional development in any direction whatever. Mr. Dyer, too, we are beginning to know, if only through the lugubrious wails and melodramatic appeals with which he has been wont to enliven your correspondence column since the Bill was taken in hand.

But there are other members of the "Executive Committee" who are not so familiar to us. However fragrant their names may be to the public and to their professional brethren in their own localities, I venture to say that those names are quite unknown to the bulk of the profession. The person who sent you that perfectly inane letter signed "Justitia" two or three weeks ago stated therein that "a well known M.P. had asked him a very foolish question about the Bill—or, at least, it was a very foolish question to put to a being having the mental capacity of 'Justitia.'" But what if some M.P. were to individually interview each of the now famous quintet, and put this question to each in turn—"What evidence can you give me to show that you have ever taken the slightest interest in the progress of your profession throughout the decades you have passed in it, until you chose to resist a proposal that you should contribute less than fivepence a week to its funds?" It would be an unkind question—and the mental picture of some of the poor things trying to answer it arouses feelings of such cruel mirth in me that I judge it best to conclude abruptly. The fact is that it is simply impossible for anyone with any inside knowledge of the profession to take such little opposition to the Bill as still lingers at all seriously. But Members of Parliament have no such inside knowledge of the profession, and this audacious attempt to magnify the importance of the opposition in their eyes should be a very serious matter indeed in ours.—Yours faithfully,

"MEPHISTOPHELES."

Several communications are unavoidably held over.

Prophylaxis and Treatment of

Tetanus.

"In all cases of deep punctured wounds about the feet, especially where there is reason to believe that soil or other extraneous matter has been carried to the deeper tissues, it is advisable to inject tetanus antitoxin. One never knows when tetanus may supervene."—*Veterinary News*, June 8, 1907, p. 364.

"That antitetanus serum is a curative as well as a prophylactic agent is supported by the indisputable evidence of many pronounced cases of tetanus which have actually been cured by the administration of adequate doses of serum."—*Veterinary Notes*, March, 1908, p. 30.

ANTITETANUS SERUM (Veterinary), P., D. & Co.

prepared with scrupulous care under the direct supervision of bacteriologists of wide repute. Has gained a world-wide reputation for efficacy both as a prophylactic and curative.

Two members of the Royal College of Veterinary Surgeons write of the "P., D. & Co." serum:—"We would not be without it, as it is undoubtedly the only reliable serum we have yet used. So far each case has recovered."

In *The Veterinary Record*, August 25, 1906, a report appeared of four cases of tetanus in horses which were successfully treated with "P., D. & Co." Antitetanus Serum after other veterinarians had advised destruction of the animals.

In *Veterinary Notes*, March, 1908, several cases of pronounced tetanus cured by "P., D. & Co." Antitetanus Serum are recorded by the Secretary of the New York University Veterinary Association.

ANTITETANUS DUSTING POWDER, P., D. & Co.

Of proved antitoxin power. Applied to wounds suspected of tetanus infection, it prevents further absorption of toxin, whilst the injection of serum neutralises that already absorbed

As Locum Tenens

M.R.C.V.S., 20 years experience, now managing large practice, would act as locum for a fortnight for a change of air. Address, 2075 V.R., 20 Fulham Rd., London, S.W.

For Disposal

COUNTRY practice in Midland County, carried on by the vendor for half a century, nearest opposition 5 miles, returns about £200 yearly, introduction given. Price £120. Further particulars to bona-fide purchaser. Address, 2074 V.R., 20 Fulham Road, London, S.W.

To be Let

TO VETERINARY SURGEONS. To be let from end of June an office between Harrod's Stores and Tattersall's. Fine opening for M.R.C.V.S. Further particulars "Equus." care of Willings, 73 Knightsbridge, S.W.

For Immediate Disposal

THE extensive veterinary practice so successfully carried on for past 17 years by the late W. O. Robertson, Selkirk, is now for sale. All books etc. open to inspection. For further particulars apply to Archibald Robertson, Springbank, Selkirk.

For Sale

MARKHAM'S Masterpiece, a very old and curious Veterinary work. Book in good state of preservation. Address, 2073 V.R. 20 Fulham Rd., London, S.W.

As Assistant or Locum

SITUATION required by thoroughly practical M.R.C.V.S., town or country. Address, 2079 V.R., 20 Fulham Road, London, S.W.

All communications respecting advertisements should be addressed to

H. & W. BROWN, 20 Fulham Road, London, S.W.

Tracheotomy Tubes

MISS JONES, successor to F. B. Jones, M.R.C.V.S., still continues to supply the Special Tracheotomy Tubes patented by her late father. Special terms to Veterinary Surgeons. Address, 86 Kimberley Road, Leicester.

Assistant Wanted

EXPERIENCED, qualified assistant wanted, prefer married man, for a wide country practice. Must be well up in parturition, and castrate standing. Best of references: sign bond. Good salary, permanency for suitable person. Address, 2072 V.R., 20 Fulham Road, London, S.W.

For Immediate Disposal

FIRST-CLASS hunting and dairy practice, large contracts, inspectorship, breeding studs etc. Terms moderate to bona-fide purchaser with a little capital. The practice is in thorough going order, returning £650 to £700 per ann. Apply, Ainsworth Wilson, F.R.C.V.S., Witham, Essex.

Locum or Assistant

CLASS D student desires situation as above. Served 4 years in large mixed practice. Ride and drive. Has done locum. References. Open July 19th. Expenses and small remuneration. Address, H. L., South-Hill Park, Hampstead, N.W.

Locum Tenens

WANTED for a week, a locum tenens (cyclist) for a small country practice in the Midlands. Unqualified man not objected to. Address: R. Murray, Market Street, Rugeley, Staffs.

Qualified Assistant Wanted

WANTED end of July qualified assistant for mixed town and country practice. No objection to recently qualified man provided he has had some experience of country work. Address, 2078 V.R., 20 Fulham Road, London, S.W.

To London Veterinary Surgeons

ADVERTISER wants assistantship with view to partnership, working arrangement, or succession. Has contracts worth £200 net. but no premises. Live out. Address, 5207 V.R., 20 Fulham Road, London, S.W.

To Veterinary Surgeons

WANTED by a qualified veterinary surgeon, first-class appointment as assistant or manager of branch. Well up in all kinds of town and country work. Can spay well. Excellent references. Address, 1207 V.R., 20 Fulham Road, London, S.W.

Assistant or Improver

PRACTICAL student wishes to get situation as above. Live in. Good horseman and castrator. Experienced and good reference. Well up in country practice. Address, "V," Royal Vet. Coll., Camden Town.

For Disposal

BRANCH, to which advertiser finds he cannot attend. Splendid chance for single energetic man. Address, 6207 V.R., 20 Fulham Road, London, S.W.

As Improver

CLASS C student, July, desires position as improver been in good mixed practice. Ride, drive and cycle. Address, 7207 V.R., 20 Fulham Road, London, S.W.

Unqualified Assistant

DESIRES engagement, thoroughly practical, good dispenser, long experience. Or would act as kennelman, etc. Address, 8207 V.R., 20 Fulham Rd., S.W.

For Sale or to Let

OLD established city and country practice in a wealthy residential hunting and good agricultural district, good house and stabling, in commanding thoroughfare, proprietor desirous of retiring owing to infirmities of age. Address, 9207 V.R., 20 Fulham Road, London, S.W.

For Sale

GENUINE, old established, mixed country practice, market town, Herts., doing about £300 per ann. introduction given. Price £70. Address, 2207 V.R., 20 Fulham Road, London, S.W.

For Disposal

MIXED and increasing country practice, returning last year about £450, with County Council and U.D.C. appointments. Established by owner about 20 years. A good practitioner could increase the returns. Price for an immediate sale £180. Terms of payment could be arranged. Address, 3207 V.R., 20 Fulham Rd. London, S.W.

Locum Tenens

M.R.C.V.S., thoroughly used to country practice and holding testimonials as to ability and general character from many practitioners, is always open to engagement when not actually filling a post. Permanent Address, "Locum," 59 Gascony Avenue, London, N.W.

Wanted

QUALIFIED Assistant for London practice. Sign bond. State age, salary required, and experience. Address, 1072 V.R., 20 Fulham Road, London, S.W.

Qualified Assistant

WANTED about the end of July a thoroughly practical qualified assistant for town and country practice. Permanency to suitable man. State age, salary required, and references. Address, 1074 V.R., 20 Fulham Road, London, S.W.

As Assistant

CLASS C student, up in July, is desirous of the above position during vacation. Three years practical experience in a large mixed practice prior to entering coll. Capable of fulfilling all duties. Address, 1076 V.R., 20 Fulham Road, London, S.W.

Wanted

GENUINE town and country practice, returning £600 per annum or over, hunting essential. Devon or adjoining county preferred, strict confidence. Address, 3107 V.R., 20 Fulham Road, London, S.W.

For Disposal

GENUINE old established town practice and shoeing business in Lancashire. Good premises, with every convenience for doing a large and profitable trade, carried on successfully for many years by owner, who is retiring. Address, 4042 V.R., 20 Fulham Road, S.W.

Saloform Pessaries.

The New Uterine Antiseptic

Highly recommended by many eminent
Veterinary Surgeons.

PRICES: Ordinary Strength, White.

4/6 per doz. 48/- per gross.

Extra Strong, Yellow.

6/6 per doz. 72/- per gross.

Sole Proprietors—

HARKNESS, BEAUMONT & CO.,

Wholesale Chemists,

EDINBURGH.

Veterinary Surgeons have for long keenly felt the want of something which could be used with good results as a Uterine Antiseptic and which at the same time could be quickly and easily administered. After many trials, and with the kind co-operation of some able Veterinary Surgeons of great experience in parturition cases, we have succeeded in producing

a Pessary made with a non-oily base which does its work efficiently and at the same time is non-irritant—in fact, soothing in its effect. They are of great use in parturition in cows or mares; and if administered immediately after parturition they will keep the Uterus clean and healthy, and prevent the after-birth becoming foul.

Veterinary Surgeons in various parts have highly recommended them, and there is an increasing demand for both kinds.

Customers are requested when ordering to state which kind they prefer.

A RECENT UNSOLICITED TESTIMONIAL.

AINSWORTH WILSON, ESQ., F.R.C.V.S.,
writes:—

"I have used the Saloform Pessaries supplied by Messrs. Harkness, Beaumont & Co., of Edinburgh, with good results in various diseases of the genital organs, both in mares and cows, more especially after parturition. They are particularly useful in retention of the afterbirth, with septic complications. It is often impossible to attend more than once a day to irrigate the uterus; in such cases it is good practice to leave one or two of the "extra strong" pessaries *in situ*. I have found them an excellent substitute for Iodoform and other well known non-irritating antiseptics. I feel justified in recommending them to the profession.

Witham, Essex.

THE VETERINARY RECORD

A Weekly Journal for the Profession.

EDITED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1200

JULY 8, 1911

VOL. XXIV.

FOOT-AND-MOUTH DISEASE.

We are accustomed to invasions of this disease at intervals of a year or two: but it is a little unusual for two apparently distinct ones to occur within four months. The last outbreak, at Chobham, occurred so recently as March last, and was promptly stamped out by the action of the Board of Agriculture. It appears just possible that the present one near Hounslow may give rather more trouble. The disease was first detected in the pigs of one farm; but we understand that it has since been found among the cattle of a neighbouring one, and of course further centres of infection may yet be discovered. There seems, however, no cause for alarm. The Board of Agriculture is taking all necessary measures, a keen lookout is being kept throughout the surrounding districts, and we may confidently expect that the same authority which has stifled so many former outbreaks in their inception will be equally successful with this one.

Generally, outbreaks in this country occur not far from a port, and always when disease exists on the Continent. Considering the numerous media which are capable of conveying infection from Europe here, and the impossibility of preventing such conveyance without unwarrantable interference with trade, it seems clear that whenever foot-and-mouth disease prevails in the nearer European countries, Great Britain will never be safe from visitations of it. Thanks solely to the Board of Agriculture, these visitations have done us very little harm of late years; but their frequency illustrates the necessity for an efficient public veterinary service. Those who can remember some British outbreaks of foot-and-mouth disease in old years, or who have seen its present ravages in another part of the world, will agree that the Board's officials amply repay their upkeep to the nation by their work in connection with this one disease alone.

THE DICK COLLEGE.

It seems that the Dick School is to undergo a development that would once have seemed impossible in connection with veterinary teaching in this kingdom. The purchase of a site of $1\frac{1}{2}$ acres, and the intention to erect new College buildings thereon at an estimated cost of £50,000 will speak for themselves to those who know how often and how seriously the activity of our training Colleges has been hampered by financial difficulties. The historic Edinburgh School had its share of these in the past, and nevertheless did good work. We shall all be glad to see this signal increase in its facilities for work.

RESEARCHES ON THE TREATMENT OF LIVER-ROT IN SHEEP.—By M.M. RAILLIET, G. MOUSSU, and A. HENRY.

Dear Sir,—If you could find room in *The Veterinary Record* for the following translation of an article on Liver-Rot from the *Recueil de Médecine Vétérinaire* of 15th May last, you will much oblige. The subject is a very important one, the disease causing a greater loss to flockmasters in the British Islands than any other two diseases together. Towards the close of last session I called the attention of my class to the first series of experiments made at the instigation of the French Government and referred to in this article, and expressed my regret that no substance had been found which seemed to have the least effect on the flukes in the liver. Should the promise of the article be fulfilled and a satisfactory remedy found for "rot" in sheep it will be nothing short of a boon to the flockmaster.—I am etc.,

J. R. U. DEWAR.

Owing to the losses caused amongst French cattle for several months through the prevalence of fluke disease, at the instigation of the Minister of Agriculture we entered on an investigation and carried out some experiments for the purpose of finding an agent which would destroy the flukes in the bile ducts.

We have already described (*Ibid.* 15th April last, p. 236) several of these experiments. One series bearing on the action of medicines known to act on the liver as aloes, calomel, salicylate of soda, and "boldo"—the others various products—phosphorus, arsenic, mercury, etc., all of which gave only negative results.

We have been more fortunate in a new series which included particularly tartar-emetic, urotropine, atoxyl, and etherial extract of male shield fern.

The sheep treated were, as a rule, very seriously affected with the disease, badly infested with flukes and had been for a considerable time with an advanced cirrhosis, and often some distomes scattered in the peritoneal cavity—after having perforated Glisson's capsule. Most of them were infected at the same time by large flukes—*Fasciola hepatica*, and small flukes—*Dicrocoelium lanceatum*. We found these two species manifested a very different resistance to the action of medicines. The diagnosis was always verified in the living animal by microscopic examination of the faeces.

With tartar-emetic and urotropine the results have again been negative; with atoxyl we obtained

in one heifer only, the evacuation of some large flukes evidently wasted.

But the experiments with extract of male fern have been, on the other hand, pretty conclusive.

To our knowledge, Alessandrini is the only one who has recorded a positive result from the employment of this agent. In two sheep very seriously affected, which died two days after the administration of the medicine, he states that the very numerous flukes collected in the intestine, in the gall bladder, and in the bile ducts were dead and already wasted; but only a mere summary is given, and neither the dose of the extract, the duration of the treatment, the number of the flukes, nor the conditions found at the post-mortem.

Our experiments were carried out on five sheep, weighing from 55 to 70 lbs., all badly infested with flukes, and at a very advanced stage of the disease. Each dose, given by the mouth, consisted of 5 grammes of etherial extract mixed with 25 c.c. of oil. Three sheep from the same lot were not treated but kept for comparison. The post-mortem of all the subjects was performed immediately after death, which is an essential condition for the true appreciation of the results.

The first received a single dose and died twelve hours after, its gall bladder and bile ducts contained 390 large flukes and numerous small flukes—all living.

The second received two doses at six hours interval, and was killed *in extremis* twenty-four hours after the second dose. The bile ducts contained numerous small flukes, all living, and 55 large flukes. Of these latter only four found in the smaller ducts were alive, the others were already wasted, stretched out, and of a yellowish green colour. The gall bladder contained 142 large flukes, dead, of which only three presented this characteristic change; the small intestine 16 wasted, and the large intestine 10 dead but not wasted.

The third received three doses at sixteen and twenty-four hours interval. It was killed three days after the last dose. The bile ducts contained some small flukes quite lively, but we did not find any large flukes in the ducts nor in the intestines. The gall bladder contained nine dead, and all wasted.

The fourth received four doses at twenty-four and forty-eight hours interval. It died seven hours after the last dose. The bile ducts contained numerous small flukes, all living, but no large flukes. The gall bladder contained five large flukes, dead and wasted, and about 50 quite lively in the peritoneal cavity, with lesions of peritonitis.

The fifth received four doses at forty-eight, twenty-four, and twenty-four hours interval. It was killed three days after the fourth dose. Post-mortem: some small flukes in the bile ducts quite alive. No large flukes found anywhere.

The three control sheep died, or were slaughtered, in the course of the experiments, and respectively contained in the bile ducts and gall bladder 178, 85, and 497 large flukes, and numerous small flukes—all living.

The alteration which takes place in the large

flukes under the influence of the extract of male fern (and a little also from the atoxyl) is rather peculiar. It starts at the posterior extremity of the body, and gains little by little the anterior regions. We sometimes found individuals with a large part of the body already greenish, stretched out and wasted, whilst the part anterior to the ventral sucker had preserved its normal appearance and the cephalic prolongation effected various movements.

Another observation which seems to us of real importance is that when the large flukes lose their vitality in the liver, the bile loses the brownish colour which is one of the characteristics of "rot," and resumes its clear greenish tint and becomes quite limpid. The brown colour is due to the material excreted by the flukes from the mouth—unique opening of their digestive apparatus.

It is well known that the elimination of the flukes represents but one part—certainly an important part—of the treatment, but it is permissible to hope for the recovery of the subjects if we can treat the animals at the commencement of the affection, and before those cirrhotic changes have taken place which are necessarily irreparable.

Summary.—Of all the medicinal agents we have tried to destroy the flukes in the liver of the sheep, one alone has seemed to give clear and positive results—etherial extract of male shield fern. Also, it seems to act, at least in the conditions in which we have tried it, only on the large flukes, and exclusively on those of the liver; it does not affect the parasites which have migrated to the peritoneal cavity. Four doses of 5 grammes each at least seem necessary in order to assure the success of the treatment.

It is expedient to add that the use of this therapeutic agent for liver rot, of which the action against worms in the alimentary canal is well known, allows it to act at the same time against other parasitic infestations of the digestive tube—more especially gastro-intestinal strongylosis.

COMPLEMENTARY RESEARCHES.

Since the presentation of this note . . . , we have repeated the treatment with male fern on four sheep, retaining as a control a fifth subject of the same lot. All these animals had been treated a month before with other medicines, but without success. Their faeces always contained in abundance the eggs of the large flukes. Each of these four sheep received daily for four consecutive days 5 grammes of the extract in 25 c.c. of oil. They were all slaughtered four days after the administration of the last dose, the post-mortem performed at once gave the following results:

No. 1. Weight 46lb. The liver did not contain a single large fluke, but presented very marked cirrhosis, proving that the disappearance of the parasites was quite recent. The bile was normal in appearance.

No. 2. Weight 66lb. We found two living large flukes in the smaller ducts, an adult and a young one, and three dead adults, wasted. Hepatic lesions moderate, bile of normal appearance.

No. 3. Weight over 70lb. The liver greatly altered contains still 26 large flukes living and one dead. Bile almost normal.

No. 4. Weight 53lb. Liver little affected, one large fluke still living. Bile of normal appearance.

No. 5 (control). Weight 64lb. Liver markedly cirrhotic, contains 296 large flukes all living. Bile brownish. In all those animals the bile ducts also contained a few small flukes living.

We see that all these results are in general agreement, and that the efficiency of the extract of male fern for the destruction of the flukes seems well confirmed.

It remains to find the exact dose of the medicine, the limits of tolerance, etc. In the last experiments we observe that the largest number of living flukes is met with in the heaviest sheep. Perhaps the dose had been rather too small for the subject. We propose to try 1 gramme for each 5 kilos. of live weight.

We are asked on all sides for indications concerning the treatment of cattle. Experiments with them are yet too incomplete to enable us to give definite directions. But they will be made in a similar manner, and with all the prudence necessary to avoid the toxic effects of the medicine. The average dose to start with will be about 30 grammes for a live weight of $6\frac{1}{2}$ cwt. to $7\frac{1}{2}$ cwt.

NILE EXPEDITION 1884-5.

(Continued from p. 11.)

VETERINARY SURGEON S. M. SMITH'S REPORT, NILE EXPEDITIONARY FORCE, 1884-85.

To the Principal Veterinary Surgeon, War Office, London.

Sir,

With reference to the recent operations of the Nile Expeditionary Force, I have the honour to submit the following report of my movements, etc.:

1. I was attached to the 19th Hussars, stationed at Abbassich, Cairo, under the command of Lieut.-Colonel P. H. Barrow, C.B., C.M.G., the regiment being ordered to proceed up the Nile on the 25th October, 1884.

As soon as the regiment received orders to be held in readiness, I applied for 400 sets of No. 1 shoes and sufficient nails, to be supplied by the Ordnance Store Department, at Kasr-el-Nil. The Regimental Quartermaster was unable to obtain this quantity, and to endeavour to make up the deficiency a number of locally made shoes and nails were supplied at the railway station as the regiment was leaving, and which I found, on examination, to be totally useless, the shoes being badly made, coarsely pritchelled, and too large, and the nails much too large for the purposes required. They were therefore returned to the Ordnance Stores on the first opportunity.

2. Besides the No. 1 shoes I actually obtained from the Ordnance, I ordered the farriers to pack all the No. 1 Store shoes and any that they had in their possession.

3. Long before the regiment received orders to be held in readiness, I suggested to the Principal Veterinary Surgeon, Cairo—Veterinary Surgeon 1st Class, C. Clayton—that a large number of No. 1 shoes should be specially telegraphed for through the Ordnance, as I expected, in case the 19th Hussars were ordered on active

service, they would be mounted on native horses. This, I believe, was done, but the shoes could not have arrived in Egypt in time. There was afterwards a great difficulty in obtaining shoes, and here I would most respectfully suggest that a smaller shoe should be kept by the Ordnance for colonial purposes, No. 1 shoes being generally too large.

4. The regiment proceeded dismounted to Wady Halfa. The portable portion of the regimental forge was taken to pieces, and conveyed with the heavy baggage. A small quantity of coal was also taken, which was afterwards almost invaluable, owing to the necessary alterations in the size of shoes to fit the small feet of the native horses.

5. At Assouan, E Troop was ordered to remain to collect a number of horses of the Egyptian Cavalry, and march to Wady Halfa. The remainder of the regiment proceeded by river in steamships. On the 13th Nov., 1884, 137 horses were handed over by Major Grenfell, Egyptian Army, to the 19th Hussars at Wady Halfa, and on the 14th 203 horses were handed over. They were mostly unshod, those that were so being roughly and badly shod by the native farriers. The regimental farriers immediately commenced to shoe, and remove the shoes of those already shod, where necessary, this work being completed as far as possible by the evening of the 21st. This, I consider, greatly redounds to the credit of Farrier-Major Short (since dead) and the regimental farriers, shoeing smiths, and assistants. All had to work very hard under most trying circumstances, the sun being very powerful during the day, and shelter unobtainable.

6. The regiment, with the exception of C. Troop, had marched from Wady Halfa by the 22nd. Sufficient shoes and nails for the 100 horses supposed to be marching in charge of E Troop from Assouan, were returned to store for them on arrival. The regimental field veterinary medicine chests and forge were sent by rail to Sarra station with the baggage, sufficient medicines being carried by each troop farrier to last until arrival at Sarra.

7. The horses taken over, though small, went through the campaign in excellent condition, considering the difficulty of forage and the weight to carry, and in crossing the desert between Korti and Matammeh they were at one time over 50 hours without water and very badly fed. Many returned from Matammeh with very bad sore backs. These were mostly cases of long standing injuries caused in former marches, large surfaces of skin having been destroyed, but not sloughed away. The cause was found to be the loop sewn on the girth strap, which was towards the body instead of towards the flap of the saddle (the saddlery was also taken over with the horses). This was altered in all the saddles; and no fresh cases occurred. In the march between Wady Halfa and Korti camp, comparatively few cases of any kind were reported, and the march of the Headquarters having occupied the days between the 22nd November and the 20th December, one day's halt at Absarat on the 4th November, one day opposite Dongola on the 9th. The 13th, 14th, and 15th were occupied in crossing the river at a camp, Shabadood, about three miles beyond Handak. No further halts were made. At times the track led over rocky mountains, and it was fortunate that the horses were well shod; at others, the track passed through sand; but at times the ground was good, and allowing of much brisker motion, though most of the distance was done at the walk. To save the horses as much as possible, the men were made to dismount and walk short distances. The resources of the country, with regard to forage, will be treated of in a later paragraph.

8. At Korti, soon after arrival, one horse (G 70) died of enteritis. A case of farcy, and one of purpura-hæmorrhagica also occurred. The last two cases were imme-

diately destroyed, and no further symptoms of farcy or glanders appeared amongst the horses during the period I was in veterinary charge. These horses, I may state, had constantly suffered from glanders and farcy, and no doubt the march had something to do with the development of this single case.

9. At Korti, owing to the non-arrival of other Veterinary Officers, I was requested by the late Major-General Stewart to give up medicines for the various camel corps, and also to attend the camels. Having only taken a sufficiency of medicine for the use of the 19th Hussars, I at first objected to give up my medicines for camels until the General decided I must do so, and that he would take all responsibility for the horses afterwards being without. I subsequently was able to obtain an unit box from Captain Maxwell, who had very few camels, and handed it over to the officer commanding the Mounted Infantry, and also a tin of McDougal's sheep dip I had was handed over for use of the Guards Camels Corps. Veterinary Surgeon, 1st Class, C. Phillips, shortly afterwards arrived, bringing a quantity of unit boxes and other stores, and was able to supply Veterinary Surgeons Bennett and Beech, who had also arrived, and took over charge of the camels. Before passing, I wish to testify to the excellent qualities of McDougal's "dip," as a dressing for wounds. Made into a weak solution with water, it was applied to the severe galls on the camels, by means of cotton obtained in the district. When time was allowed, and attention paid to cleanliness, wounds commenced to rapidly heal; but owing to the necessity for working all the camels, this was almost impossible, as the majority of them had saddle injuries.

10. The regiment at Korti became divided into three divisions, one proceeding with the River Column, one across the Desert, and one remaining at Korti to become the escort of Lord Wolseley, when he should cross the desert. This division was not required for this duty, although twice held in readiness to proceed. I was left with this division. E. Troop was still at Wady Halfa, and various other stations. The squadron proceeding up the river because almost destitute of shoes and nails, only a few sets being procurable at Korti, and our stock being exhausted in sharing those remaining before the regiment was divided. The horses of this division consequently returned to Korti almost shoeless, and with many horses foot-sore. The constant marching to and fro, over rocky ground, will account for the excessive wear. Constant applications were made for further supplies of shoes, and on the march up the Officer Commanding had sent in an estimate for shoes and nails, etc., that would be required per month for the use of the regiment. Not, however, till March, 1885, could any be obtained, and then only sufficient to partially shoe the horses, so that they might march to the various summer quarters. The horses of the Desert Column returned very much debilitated, owing to the great privations they had undergone, and the very hard work they had performed. Many horses either died or had to be destroyed for debility on the return march. Several horses were also killed in the various engagements that took place.

11. After the retreat from Matammeh, the regiment was concentrated at Korti, a part of E Troop having joined from Wady Halfa. It was, again, however, divided, to take up summer quarters at the various stations along the Nile, the Headquarters and two troops proceeding to Dongola, where they were afterwards joined by the remainder of E Troop. This troop had been performing transport duty at various stations. Applications were again made for shoes and nails, this being a good opportunity to get the whole regiment thoroughly shod, in case they were required to suddenly march. But owing to the necessity of getting all the clothing for the men forwarded to the various stations before the

Nile became at its lowest and preventing navigation, the transport of other stores was delayed. In April 100 sets of shoes were obtained, with a sufficiency of nails. I immediately ordered the two farriers to convert all the hind shoes into fore, and then equally divided the 200 pairs thus obtained of fore shoes between the various troops, that the worst cases of each might be shod up, at least, on the front feet.

12. Besides the regimental shoeing, farriers were required also to shoe staff horses, and a number of horses that were still in charge of the Egyptian Army. (At one time one shoeing-smith was detached for staff duty). This, of course, tended to lessen the supply of shoes available for the use of the regiment.

13. A few remounts were purchased from Officers at Dongola, Shabadood, and Korti, and a number of horses also were handed over from Lord Wolseley's Egyptian escort, and some that Major Grenfell had brought up to Korti on special duty. There were no suitable remounts to be obtained from native sources between Wady Halfa and Korti Camp. At Dongola there are a few horses, but the natives prefer to keep them. Horses at other places were small and badly shaped.

14. With reference to forage for the horses, the Commissariat, where possible, supplied barley or dhourra, and on the march, where it was thus obtainable, two or three days' rations were carried on camels. At some few places the Officer commanding was able to purchase barley, but in no great quantities. Dhourra, however, could be bought at most stations, depending on the amount of cultivated ground along the river banks. At some places not even a few stalks of the dhourra could be obtained without pressure on the natives, the supply being so scanty and all the growth being required for the native cattle. At some stations we were able to obtain either green or dried dhourra straw (wheat and barley), and green beans. At Matammeh the horses existed for some time on this green bean foliage alone. On the whole, it will be seen that no dependence can be placed on the local production. At Ajadeh, Argot Island, Dongola, Shabadood and Korti, the largest supplies were obtainable; also at a bend of the river beyond Kibar, some excellent barley was obtained.

15. The previous history of the horses should be taken into consideration, to account also for the debility occurring in the Desert Column, for it has been said that these horses were so exhausted that at one time they were useless. Most of them had been through the former Suakin Campaign, and many were even the remains of the Egyptian cavalry horses of the 1882 campaign.

16. There were a few mules attached to the regiment, and these animals seemed to stand the climate very well indeed. They were used for carrying the cooking pots and baggage necessary to march with the various detachments, the camel transport generally starting earlier and arriving rather later in camp.

17. With reference to camels, I was not constantly in charge of them, except those required for regimental transport. At various times I was asked for opinions concerning them, and at Korti and Dongola had various charges. There is no doubt that the strength of the camel was much over-rated and taxed. He was loaded and expected to carry much more weight than should have been the case. This was specially noticed after having seen the amounts carried between Wady Halfa and Korti, and comparing them with the loads and weight carried by the native friendly tribes between Korti and the Desert Wells. The estimate of weight by the soldiers seemed at times very vague, more often 600 or 700lb being loaded than 400lb. The saddle for the camel should, in my opinion, be very differently constructed; more attention should be paid to the natural conformation of the animal. The lumbar region was not "fitted" at all, the transverse processes of the verte-

bræ in an enormous number of animals becoming diseased or broken, and very large galls existing there, rendering the animals either useless, or resulting in septicæmia, or pyæmia, and death. Again, various sizes of saddles should be kept, so that a small camel should not be obliged to wear a large saddle, as was the case when the Light Division of the Camel Corps had to perform transport duty, where the part about the hips and sacral region became much damaged. The arch of the ribs was also a great seat for saddle galls, some being frightfully severe. Abscesses were constantly forming, and owing to their not being operated on, often became vast open wounds, the skin being completely destroyed; on removal of the saddle patches of the skin would be found adhering to the lining pads. The work of the campaign being so heavy all camels had to be used, though many were unfit to work owing to severe wounds and their general bad condition; the result being that many of them that died were found to have suffered from blood poisoning, with the accompanying fever—they marching on until they dropped and died.

The camel being an extremely nervous animal in temperament, often came in for abuse and brutal treatment from his various attendants; one case I saw of the jaw being fractured by a blow, the animal having to be destroyed as useless for further service.

The practice of tying one camel to the one before him on the march, and in his turn to the one behind, should be discountenanced, it leading to injuries to the tail and jaws, and oftentimes a willing or strong camel having to drag a tired or debilitated one. The tribesmen doing transport work with their own camels always allowed them to travel free. The necessity for keeping the camels tied on picket lines was, no doubt, to a great extent the cause of much of the skin disease that existed—the camel, for his general health, requiring to roam about and graze at will. The difference of management was easily noticeable among the camels of the friendly tribes, they being free from skin disease and galls, and in much better condition than the Government camels. Of course, these camels had not been subject to the long and trying march up the country the Government ones had. Again, with regard to watering; there seemed to exist an opinion that as the camel was required to go long distances and periods without water, he should be constantly practised in going without. This I consider a great fallacy: he should be allowed to drink whenever opportunities occur. If the camel is made to travel long distances without water, he has to suffer afterwards. He can certainly travel long periods without water, owing, in my opinion, entirely to the size of the rumen; but so can cattle, as was seen when the contractor of meat drove some bullocks from Korti to the Gakdul Wells, and beyond, without water. The camel, no doubt, like all other ruminants, requires plenty of water, and if he is kept without it he suffers sooner or later from the deprivation. I believe that, but for the difference in the arrangement of the foot, the bullock would travel as long as the camel, provided he was accustomed to travel without water.

Great patience should be exercised in watering camels; they will often not drink before the sun rises or after sunset, and many require a long time allowed them, being very shy.

The camel seems an animal very susceptible to paralysis, several cases of which I saw. Concerning the diseases that generally occurred, I leave their consideration to those Veterinary Officers who were constantly attending camels.

18. The animal chiefly depended upon by natives, besides the camel, is the donkey. Great numbers exist all through Upper Egypt, and the provinces as far as we went; he is active, strong, and able to carry a heavy load. I consider him a most useful animal, and he might, perhaps, have been utilised with benefit to a

much greater extent during the recent operations up the Nile.

19. There is no doubt that the number of camels employed was far too small at the first, which was probably owing to the difficulty of feeding a larger number; but, providing that forage could have been obtained, I believe it would have been more economical to have purchased greater numbers.

Before proceeding up the Nile, being in charge of the veterinary medicines, I had to prepare the first portion of the veterinary unit boxes, some 60 odd in number, and also to prepare and pack the cases of carbolic oil; to perform this duty I had to obtain the services of the late Farrier-Major Short.

In cases of expeditions similar to that up the Nile, a more portable form of forge would be most useful; so that when a Cavalry regiment became so much divided, each division should be in possession of one, and so be independent. I have, etc.,

S. M. SMITH, Veterinary Surgeon,

Army Veterinary Department.

London, 15th September, 1885.

LIVERPOOL UNIVERSITY VETERINARY MEDICAL SOCIETY.

A general meeting was held at the University on Friday, June 16. Present: Messrs. J. T. Share-Jones, President; W. Woods, Wigan; J. B. Wolstenholme, G. H. Locke, Manchester; Dr. Annett, D. C. Matheson, H. Sumner, F. Jones, W. Quiggin, and A. Richardson, Liverpool; Hewetson, Southport; Ball, Ormskirk, Ward, Little Sutton; Dobie, Birkenhead; and W. J. Fletcher, Wrexham.

Apologies for non-attendance were received from Sir Robert Boyce, Messrs. S. Jackson, E. Faulkner, A. Taylor, J. Storrar, P. Carter, R. Hughes, and H. Holroyd.

The minutes of the previous meeting were read and confirmed.

Mr. FRANK WARBURTON, M.R.C.V.S., was nominated for membership: Proposed by Mr. F. Jones, seconded by A. Richardson.

The proposed rules for the reconstituted N.V.A. were considered and approved subject to amendment to Rule 2, Section 2, to read "for the discussion of subjects of veterinary interest," and Rule 8 to read following Agricultural Society—"or any ordinary member of any existing Veterinary Society." The object of this amendment being to permit members of the medical profession who are members of existing Veterinary Societies to become members of the N.V.A.

A letter from W. Watson Rutherford, M.P., was read expressing regret at his unavoidable absence and advocating increased Government assistance for veterinary work.

PRESIDENTIAL ADDRESS.

JOHN T. SHARE-JONES, F.R.C.V.S., M.S.

In the first place I must offer my thanks for the honour you have conferred upon me in electing me President of this Society for the coming year. In accepting the office I think I may claim a fair acquaintance with the ups and downs of the working of a Society of this kind, for for some years it was my privilege to occupy the post of Secretary, and that is the office which above all reveals the many difficulties which have to be overcome to ensure what may be termed a successful year.

I presume the primary object of all our societies is to promote the welfare of the profession to which we

belong, and to increase our utility to that greater community of which we form a small part. Thus we discuss professional and topical subjects, and at times forward recommendations as the result of such discussions to those quarters where they might take effect. We are in effect a kind of guiding hand, and although we have no authoritative official status there is no doubt that our work produces, though slowly nevertheless surely, beneficial results, and this indicates the necessity for a careful sifting of all the material brought before us.

There are so many subjects which present themselves when considering the question of a presidential address that much difficulty is experienced in making a selection. However, I propose dealing briefly with the question of the veterinary surgeon and the public.

One of the greatest questions with which the profession will be confronted in the near future will be the modification and, if necessary, amplification of its Educational curriculum to meet the increased requirements which will be demanded in connection with the great question of Public Health. This subject is at present before the country in a light such as it has never been before. The public are being educated rapidly on its economic side, and the lay mind is easily grasping the fact that it is a matter which has the greatest bearing upon the nation's welfare.

The subject is no longer regarded from the point of view which is mainly dominated by sentiment, but is being seriously taken up by the hard-headed business men, who are appreciating its far-reaching effects upon our trade and commerce, and the immense drain upon the ratepayers of this country which our laxity in dealing with preventable disease entails. Education in this respect is progressing rapidly. The question is now placed alongside such great questions as national education, our Tariff system, and so on, on our political platform, which with its faults remains the greatest of our educative forces, for it reaches thousands of our people which no other educative influence affects. One has only to mention on a public platform the fact that one out of every three persons engaged in occupations who die between the ages of 15 and 65 is killed by tuberculosis, and draw attention to the number of applications which are made as a result to our Boards of Guardians for relief for the widows and orphans of the deceased out of public funds, and the audience will immediately see the economic value of eradicating this disease. We have in Wales an educative and preventive campaign against tuberculosis. It is our National Memorial to King Edward, and has been initiated and is carried on by voluntary effort. In this campaign it has been my privilege to speak on several occasions, and what struck me more than anything else was the ready manner in which the people appreciate the intimate relationship existing between the life of man and the lower animals—particularly the domesticated animals which man has selected to live around him. To the intercommunicability of disease between the various species including man, and the risk which man runs by infection from the lower animals the public are now becoming enlightened, and the time will shortly arrive when through their duly elected representatives the people will assuredly demand that comprehensive dealing with this question which other great national subjects receive.

This, then, is our opportunity to show our utility to the community. Preventive medicine is the medicine of the future. No longer are practitioners of human and veterinary medicine regarded in the light of men possessed of mysterious secrets, handed down from generation to generation in Latin prescriptions. Their skill in operative surgery, and ingenuity in preventing disease are what are now respected. We have our part to play, and this part is by no means the least important.

As a young and small profession, I fear we are not public-spirited enough. We seem to be waiting for some good Samaritan to offer the hand which will raise us and keep us in an exalted position amongst the learned professions—a hand which never seems to appear.

Like all other bodies of men, our first duty is to be of service to the community to which we belong. The administration of public affairs demands the voluntary services of men drawn, if possible, from every section. These men give their time and labour in the majority of cases cheerfully. To be placed on the Bench and to receive occasional invitations to public functions are but a very inadequate recompense, and the public man gets little direct return for the self denial which he is called upon to make. Ample repayment comes, however, in an indirect manner, which few seem to appreciate. The presence of a member on a public administrative body calls attention to the profession or business to which he belongs—it is a kind of natural advertisement, and if he should display ability, then not only is he appreciated at his true value as a man, but that appreciation is extended to the section to which he belongs. How useful it is to have a member of such a profession or line of business on our Board or Council? is a phrase of every day use. The adaptability of the various members to the different branches of work is plainly in evidence when the members of Committees are being elected, and just as the surveyor, builder, or engineer finds a seat on the Building Bye-laws or Highways Committee, and the educationalist on the Education Committee, and so on, so do the practitioners of human and veterinary medicine naturally gravitate to the Health Committee. Then the opinion of those whose work is most closely allied to the matter in hand receives deference, and, speaking generally, the affairs are administered by the Board and Councils as a whole in accordance with the opinions expressed and advice given in Committee by those who may possess expert and technical knowledge.

It would be well for us as a profession to ask ourselves the question, Do we do our duty by our fellow men in this respect? I am afraid there would only be one answer, for I know of no profession or line of business which is so poorly represented as we are. There are gentlemen of my acquaintance who would ornament a seat on any public body. The public suffer through their withholding their services, and the profession loses one of the most potent factors which elevate any profession in the public eye, for the public are kept in a state of ignorance as to the real value of our work.

To me the peculiar appointments frequently made, and extraordinary actions often taken when matters appertaining to our work are concerned, are in no way surprising. The steps are taken in the dark, and there is a lack of guidance from a source which the people have every right to expect. The highest degree of efficiency in administration is only attained when our public bodies are representative, as far as possible, of every section of the community. To take our fair share in the burden of public administrative work appeals to me as the most legitimate and generally accepted method of enlisting public sympathy towards our own work.

The great branch of public health work, which we claim to represent, will certainly be dealt with. The rapid popular spread of the great science of economics will demand it, if all else fails. Whether it will be allocated to us as a right or not rests in a great measure with ourselves and the part which we are prepared to play in the game of life generally. It will not be for us, any more than it will be for the medical men, sanitary inspectors, butchers, or farmers to say into whose hands the various branches of the work shall be committed.

That is a right possessed by the people themselves, and they will exercise it through their own representatives.

Then our further duty lies in rendering ourselves highly efficient in order that the public may get a just return for the funds which they will be called upon to subscribe. If we are called upon we must give them of our best. To attain this object there should be complete sympathy and co-operation between the educational centres and those engaged therein and their brethren in practice. The ploughman in the field is as essential to the welfare of the farm as the cowman in the yard. Practitioners have opportunities for gauging public opinion and estimating public requirements which render their advice and help to those engaged in the schools invaluable. On the other hand, the schools with their museums, laboratories, dissecting rooms, and so on, I think I can say with fairness are centres to which the practitioner can look for assistance in unravelling those knotty problems with which he is so frequently confronted. Our interests are practically one, our object the same—the uplifting of our profession, and the enhancement of the utility of our work. If we advance we do so as a whole and bound together by reciprocal sympathy and support.

We need go no further than the institution in which we are now meeting to see how this mutual help and support pervades other branches. Take the broadest case. To the children of Liverpool citizens who have been overtaken by misfortune this University makes grants to assist them to enter one or other of the professions. On the other hand, the citizens of Liverpool make an annual grant to the University out of its public funds. A reference to the University Calendar will show that most of the professions which are here represented have linked themselves to the institution, in that they have instituted scholarships, both undergraduate and post-graduate, have assisted in the foundation of chairs, etc., with the result that they have secured a permanent association with the University, and have acquired the right to assist in indicating the lines upon which the work shall be carried on and degrees granted. Moreover, through their graduates, each of these professions becomes part and parcel of the University, and the solid foundation upon which their relationship is based will maintain this in perpetuity.

What is our position? The history of University veterinary education in America reads like a drama. Years ago the few with most advanced views saw the advantages of being associated with the Universities. Schools were attached to them in a kind of semi-detached fashion. But they were built on the sands, and one after another fell from financial starvation. Then came a great revival. The profession recognised the fact that it was part of a great community, and that it was a contributor to the public funds. The veterinarians saw that, as a section of the people, they had a duty to perform to themselves and that was to secure the benefits and advantages which were conferred upon other branches of learning through the medium of the Universities—the channels through which public funds for the purpose of higher education were disbursed. What is the result? Through enthusiastic and complete co-operation they have become an integral part of the University, for there is scarcely a University of repute in America which is without a properly endowed veterinary school, and which does not grant veterinary degrees admitting veterinary students as members of the University. Their foundation is now upon the rock, and the manner in which the work done in the schools is linked up (associated with) to the commercial pursuits of the nation in the foundation of the numerous bureaux of animal industry and experimental stations is ample testimony to the great national asset which they have now become.

Australia has followed suit. The University of Melbourne has its State-aided veterinary school, and grants veterinary degrees. But what of Britain? Well, it is always said that she moves slowly. She has certainly moved with deliberation in our case. But as I said at the outset, it is my firm conviction we have ourselves to reproach in great measure.

I don't know, but it seems to me that there is a double basis for granting a degree and conferring University benefits and recognition on a profession, one is the amount of genuine enthusiasm and public spirit displayed by that profession towards such a project. The other is the field for research work in problems, the solution of which would benefit man, which the work of the profession can offer. Well, as to the first point, we can do much. If money is required we should be prepared to contribute our share as we can afford. We want more Dicks and McCallums to stimulate support from others outside the profession.

As to the second point I have no doubt. Whilst the advocates of the richly endowed pure science who disdain applied knowledge, are searching about, frequently in vain, for problems to solve, whilst they are attempting to gather a harvest from a soil which has been tilled and tilled until in many cases it is now almost barren, we have a whole territory of practically virgin soil to offer. Start a research worker in any of our subjects and he will be positively amazed at the amount of work to be done. His difficulty will be not to find a problem but which problem to deal with first. Here is a soil the tilling of which will bring forth a fruitful harvest—a harvest the garnering of which mankind awaits.

Yes, on this second point our claim is good for we have an area for research to offer which for the possibilities of fruitful results is second to none. Yet there is not a worker in this field in any veterinary school in this country whose post is properly endowed for the purposes of research. At present, so far as research work is concerned, we are like labourers endeavouring to harvest a field of hay in their by dodging the showers in the evenings. Results cannot be expected unless our workers have an equal chance with those in other branches.

London University grants a degree in Science. Our Edinburgh *confères* are moving to get a Veterinary Degree. From the bottom of my heart I hope they will succeed. Whether the University of Liverpool will grant one rests to a great extent upon the members of our profession in Lancashire (yes, the first day I came to Liverpool a member of our profession speaking with pride, said that when Lancashire set her hands to the plough she never looked back), the men of Yorkshire, Cheshire, and Wales.

The securing of University degrees by all our Veterinary Schools will bring with it power. It will attract labourers into our field of research, and will secure for our profession an adequate share of those public funds for educational and research work which are at present being diverted into other channels. It will raise the value of the professional stock in this country, and we shall become a much greater national asset. Our repayment for any effort we put forth will be tenfold. If they are only granted to holders of the Diploma of the R.C.V.S., then will the one portal system and the power of our own governing body be maintained.

Let us for a moment examine superficially our present curriculum and see how far it meets the demands which are now, and those that will in the near future, I hope, be made upon us.

Taking all the subjects, from the preliminary examination to the final, they may be placed into two categories, namely, those which are studied with the object of developing the mental faculties, and those which have a direct and particular application to the work which our license entitles us to practice. Now

we are drifting daily away from the æsthetic aspect of knowledge and more towards its utilitarian side. This is so in our system of elementary education as is evident in the introduction into the curriculum of such subjects as domestic economy, woodwork, cookery, etc., subjects which not only develop the faculties of perception, but have a direct application to matters of after, everyday life.

With regard to the first category, the preliminary subjects, since we demand a knowledge of these as an indication of mental training and capacity—an indication that the mind has received that preparation which renders it suitable for the reception of the particular knowledge which is to follow—then it necessarily follows that there should be some uniformity in the standard demanded. Judging from the predilection which students have for certain qualifying examinations, it strikes me that there is room for much improvement here, and that the standard set up by the various examining bodies whose certificates we accept is not an equitable one.

The subjects in the second category are presumably taken during the four years intramural course. Considering the immense ground to be covered this period is very short, and the time may soon arrive when an extension will be necessary if our men are to be adequately equipped for public service. At the same time there is much work done, particularly in the first year, which, strictly speaking, belongs to preliminary study, and the applied portions of which are recapitulated later. When the eyes of most men are focussed upon the three score and ten years which they have to run, it is time to avoid anything in the nature of unnecessary overlapping. Utility should be our watchword, and application our instrument. The amount of information conveyed during our course is most extensive. But it seems to me to be somewhat heterogenous, and that we do not make the most of the subjects—we do not direct sufficient attention towards welding the information into a complete whole. Some years ago I called attention in a paper read at Rhyl to a lack of connection between anatomy and surgery, and advocated the institution of a course in surgical anatomy to link up thought and show the logical connection between the subjects. In two of our schools, to my knowledge, I am glad to say such a course is now given.

Time will not permit me to go over the whole course. My esteemed predecessor showed last year how the veterinary surgeon could enhance his value to his clients by the application of dietetics; but there is one branch of work in which I have no hesitation in stating that our training is wholly inadequate, I refer to the inspection of meat. I speak primarily as a veterinary surgeon, but one has an intimate knowledge of farming and butchering. The veterinary surgeon is the man to do this work. In his course are the subjects which can be applied to it with the greatest advantage. But unfortunately they are not applied. We lay a glorious foundation and upon it erect a superstructure of wood without even pinning it down. It is a structure which does not appeal to the architectural critics who cannot see the foundation. Meat inspection is not a subject for a single short course. Let us build an edifice in conformity with the foundation by giving a number of short courses, specially applying the subjects which form the foundation to the actual practice of the work—applied clinical instruction, applied pathology and bacteriology, applied anatomy, and so on. We should deal similarly with our whole curriculum, then we shall be giving that comprehensive interpretation to the subjects which their great importance indicates will be required of those who will take charge of the work in this what has been termed "The Dawn of the Health Age."

Mr. J. B. WOLSTENHOLME in rising to move a very hearty vote of thanks to the President for his address, said: As we get older we were inclined to view things from different standpoints. Regarding the suggestions made by the President respecting modification of our present curriculum, he felt much depended upon what the members of the profession and what the nation proposes a veterinary surgeon shall be. If we were to be worthy of the name of a profession and take our stand side by side with the sister profession we must make such progress as to entitle us to this claim. Any such progress would of necessity involve lengthening the curriculum to five years. This may seem a somewhat alarming suggestion in face of a general decline in the number of students entering our schools and the rapid substitution of mechanical haulage for horse traction. But thunderbolts always came in summer time! At the present moment the medical profession is seething with unrest through the action of one of our Statesmen. The position of the medical practitioner has to be faced from different points of view, but ultimately the nation will determine the nature of the position he shall occupy. We are all children in the great national family, and there is a growing tendency on the part of the State to assume its paternal responsibility for our general well being. There seems reason to anticipate that the future of the medical profession will consist largely of service such as that of policing, and fighting fire. Preventive medicine and applied hygiene are becoming increasingly important.

If the members of our great national family render that service in the right spirit, and not in that of German officialdom, we have nothing to fear, and as there is such close association between animal and human diseases, and the general work of the veterinary surgeon and public health we, as a profession, must ultimately take our place side by side with our medical brethren. This being so our prospects are most hopeful.

Naturally the question arises as to how far the nation can institute service for all our members. This, fortunately, is receiving the attention of official bodies throughout the country. What we want is not less but more officialdom in veterinary matters. There must be a general increase in the appointment of whole-time officials and a general system of decentralisation in the administration of Animal Diseases Acts.

He welcomed the President's reference to the inadequacy of the financial facilities offered to our profession for research work. No department of science offers such a wide field for interesting and profitable research. There was every reason to believe that work in this direction would assist largely in the solution of many pathological problems. This class of work is becoming increasingly necessary. He instanced the research in matters relating to pigmentation, melanotic tumours, in relation of loss of colour of hair, how fats are taken up from the alimentary canal and distributed, etc. It was not for lack of brains—of efficiency—that these problems were not solved, but for lack of opportunities of research. An ordinary practitioner cannot possibly do much research work, and up to the present neither State or public aid had been forthcoming for these purposes.

Mr. W. Woods seconded the vote of thanks. In doing so he wished to associate himself with the ideas expressed by the mover. He felt that the President had introduced matters of vital importance to the profession, and was glad to think through the veterinary press they would be brought before the profession as a whole. He regretted that the occasion did not seem the most suitable to enter into a further consideration of the address, and expressed the hope that at some future time the suggestions made would receive the careful examination their importance demanded.

On putting the motion to the meeting it was carried unanimously with acclamation.

The PRESIDENT briefly replied, thanking the meeting for their expression of thanks, and said he would welcome a further discussion on his address should the Society so determine.

ANNUAL DINNER.

The dinner was held at the University Club in the evening. Mr. Jno. T. Share-Jones, the president, occupied the chair, the principal guest being Mr. E. T. John, M.P. Others present were Professors Annett and Buchanan, Dr. Mussen, Messrs. Bull, Ormskirk; Marsden, Fletcher, Wrexham; Woods, Wigan; Sumner, Shepherd, Frank Jones, Arnold Richardson, Liverpool; Hewetson, Southport; Wolstenholme, Manchester, etc.

Mr. BRITTELBANK (President of the Lancashire Veterinary Medical Association), in proposing "The Medical Profession," said he had often been asked to come to the Liverpool Veterinary Medical Society, and if he had not done so now the Lancashire Association would have felt that he was breaking a promise he had given that he would visit them when an opportunity presented itself. As to the medical profession, it was one that he had worked very closely with for a good many years, and he had seen a great deal of the difficulties which attended its work, particularly on the preventive medicine side. He could not help thinking as he came along from Manchester of the enormous work which had been done in this city by the Preventive Medicine Section of the University. He referred to the Tropical School. Huge tracts of country had been opened up to commerce with comparative safety as compared with the condition of affairs not so many years ago. There were many gentlemen in that city to whom we owed a great debt of gratitude, and he was quite sure as the years went by the world would realise what these gentlemen had done not alone for the public health but also for commerce, because there was, after all, a very great commercial side to this question of public health. Each life was worth a definite sum of money to the nation, and each life saved was a distinct asset, but the medical profession were a national asset, and no doubt a very prominent national asset. At present there was a considerable agitation going on, and they sincerely wished them a happy issue out of their afflictions. (Hear, hear.) Speaking for the veterinary profession, a great many of them regarded themselves as a sort of younger branch of the general profession of medicine. Their aims were the same—the alleviation of suffering—and they looked forward with pleasure to the aid which they might expect from the medical profession as the years went by. (Hear, hear.)

Professor ANNETT, in replying, referred to the serious illness of Sir Rubert Boyce, to whom, he said, they owed almost entirely the existence of their Society. Why he should have been asked to respond to that toast he did not know, for the whole length of his career as a medical practitioner stretched over a vast period of two weeks. (Laughter.) For two weeks he was a medical practitioner—for the rest he would not say he was a veterinary surgeon but a veterinarian. Almost immediately after he obtained his licence to work he had the good fortune to be presented with a travelling 1851 scholarship, and after that he passed some six months study with Sir John M'Fadyean in the London Veterinary School, and from thence he travelled on the Continent. He went to Berlin, and there was associated with Professor Schütz, professor of pathology in the veterinary school, and with Professor Koch, of the same institution in Berlin, an institution whose members studied both the human and veterinary science, in fact the study of those two sciences should not be separated. Medical science could hardly exist without veterinarians. It had been his pleasure, almost his ambition, through-

out the 15 years in which he had been more or less associated with veterinary matters in this city, to foster as much as possible a good feeling between the two professions. (Hear, hear.) He looked upon himself as a sort of intermediary between the two. He had hoped that the progress in that direction would have been greater, and he would like to offer every assistance to members of the veterinary profession in joining with the members of the sister profession in cultivating as far as possible what one should call the science of medicine rather than the medical science—that science which underlies both professions, and by means of which they should bring about benefits to mankind, benefits to the country, the city, and themselves. (Applause.)

Dr. MUSSEN proposed the toast of "The Veterinary Profession." He remarked that ever since the veterinary school was established seven or eight years ago he had had the privilege of being one of its staff. Mr. Brittlebank had alluded to the help which the two professions gave each other. He cordially endorsed that. In the department over which the Medical Officer of Health presided they had had nothing but the greatest help and assistance in anything which had been proposed with a Public Health object. He thought the classes relating to tuberculosis had been a success, to a large extent, owing to the way in which the veterinary profession had assisted them. The medical profession and the veterinary profession had a great deal in common. It was a great pleasure to be connected with the profession, it was so progressive. A young profession was always interesting, it had got possibilities in front of it. The medical profession was hoping to go ahead, too, but he thought their profession was to a large extent dependent on how they were helped by the veterinary profession. (Hear, hear.)

Mr. HENRY SUMNER, replying, paid a tribute to the work accomplished by Sir Rubert Boyce as being the means of improving the education and thereby the status of the veterinary surgeon, that their members should be put on equal lines with the other learned professions. Their profession was a young one, it was a small one, and it was going through a most critical period of its life. The governing body had ceased to have sufficient funds to carry out its duties in a proper and efficient manner. Those funds hitherto had been gained by the profits of its examinations. Now, through various agencies, the students of their schools were diminishing, through the increase of knowledge and the necessity for a wider field of examinations, the cost of examinations was increasing, and instead of a profit from examinations the governing body sometimes made a loss. The funds of the College were insufficient, only quite a nominal sum. The assured income was about £140 or £150, consequently it had been necessary for them to apply to Parliament for powers to charge an annual registration fee. Hitherto they had been a free profession—after they had gained their license to practice there had been no further call for any subscription. He believed that that very night the Veterinary Surgeons' Amendment Bill was before the House of Commons, and if the opposition was such that it was rejected the position of the Royal College would be one of acuteness—one of great seriousness. He said that feelingly, because they as a profession had prided themselves that they had one important system—they had one license which had been obtained through a good deal of stress and storm and very many difficulties. Now it was apparent that if they did not get this increase of funds the time had come when they could no longer claim the right, and the sole right, to license veterinary surgeons within these realms. That, unfortunately, was a matter upon which the profession was not absolutely unanimous. There was a small number who still resisted the change, and who still objected to giving power for charging for registration. Considering the lot of the veteri-

nary practitioner it would, he said, perhaps undergo a very considerable amount of change. The time had come when they should not be merely repairers of the lower animals, but when the public would expect them, as experts in animal diseases, to be able to advise local public bodies both in the administration of the local Acts pertaining to animal diseases, but also to be at the right hand of the medical officer of health to say which was and which was not flesh that was fit for human consumption. That was one branch; another was the administrative one. They knew that the Animals Diseases Acts were administered from one central authority, the Veterinary Department of the Board of Agriculture, and they were administered, probably many of them thought, by a considerable shortage of qualified veterinary surgeons. He thought the probability was that within a few years the profession would be called upon to take up many of those administrative duties which were now given to gentlemen who were not educated as veterinary surgeons although they might be estimable gentlemen in the way of enforcing bye-laws and regulations. Another point considered at their county meeting at Manchester was as to whether the time had not come for passing a resolution approving of the decentralisation of the veterinary work, and if it had arrived that the County Councils should be the administrative bodies, and that they should employ a considerable number of veterinary surgeons as whole-time servants. These were things which showed that their vocation was changing, which showed the examining body in London that it was necessary the curriculum should be brought up-to-date, and that their new men should be fitted to hold any of the posts which in the future would come within their reach. Sir Rubert Boyce upon a memorable occasion once said "It is for you to capture the posts—the administrative posts." He (Mr. Sumner) said it was for them to be fitted to hold the posts when they captured them. (Hear, hear). As to the fitness of the veterinary surgeon for public offices they looked with pleasure upon the success which had attended the veterinary department of the Corporation of Liverpool; they had done some fine work in Manchester, so they had not failed to show the public that they were fitted for those position which in the future might come their way.

Now there was a question as what the schools were doing. The examining body was right in demanding a high standard of knowledge for the candidates who came up for their respective examinations. What were the schools doing? And what had been the influence of the coming of veterinary teaching into that University upon the teaching of other schools in Great Britain and Ireland? He thought he could say without fear of contradiction that the very fact of veterinary education becoming part and parcel of the work of the Liverpool University had had a most salutary influence upon our schools, which up to that time looked upon that effort with a not altogether friendly eye. The schools, like the parent body, wanted money, but from what source was money likely to be obtained? What was their claim upon the Government for beneficial treatment? What was their claim upon the Government that they should receive a share of that money that was expended both by the Board of Agriculture and the Board of Education? He thought they could claim that they were a necessity for the well-being of the masses—a necessity in the interests of Public Health. He thought they could claim that they were absolutely necessary to be the hand-maiden of Agriculture, so he considered they had a claim both on the Board of Agriculture and the Board of Education for some help to go on, and if possible increase the efficiency of the different schools. The Royal Veterinary College got the handsome sum of £800 a year from the Board of Agriculture. Why, then,

should not they get £400 or £500, or a sum in accordance with the number of students for the advantages which they afford. (Hear, hear).

Mr. W. Woods also responded. He said it was in 1792 that the first veterinary school was established in this country, and then a Frenchman had to be sent for to teach veterinary science here. That school owed its existence to four medical men, so that they not only owed their individual existence but their professional existence to medical men. At first the education was probably very poor, but now they could say with a certain amount of pride that the general education of a veterinary surgeon did not leave a very great deal to be wished for, seeing that they accepted no certificate but what would qualify a student for the medical profession. And they could not accept anything less, for the day had gone by for a veterinary surgeon to be an uneducated man. No one degree was higher than another so far as the licence to practice was concerned. It was not always so. He thought the unanimous feeling of the profession was that the one portal system should never be abolished until there came about a State veterinary examination. He would like to see a State examination for the medical as well as the veterinary profession; he believed it would be an advantage to the medical profession. The veterinary profession had been made use of to a certain extent by the Government in the suppression of contagious diseases, and he felt they had a great future before them in that direction. At the present time the administration of the Acts for the suppression of contagious diseases and the thinking out of the laws all came from London. It was quite easy to think that different parts of the country would require different treatment. Let them take the case of swine fever, which was on the increase, and which the Board of Agriculture had done a great deal to try to suppress, and which they were suppressing in some parts and were not in others. If that work were decentralised, if there were organised veterinary sanitary administrations of different parts of the country with Veterinary Officers of Health of counties, and if those counties were allowed to deal with contagious diseases within their own areas they would recognise some reasons why the Board was not suppressing and not stamping out contagious disease, and they would be able from their knowledge of the local conditions to enact laws subject to the Central Board in London, which would be more effective in stamping out swine fever and anthrax, which was on the increase. The cause of anthrax was probably different in different parts of the country. In some it might be imported in hides, while in others where they knew it was increasing and where there were no tanneries, it was probably imported through manures.

Mr. J. T. SHARE-JONES (the President) submitted the toast of "Our Guests." He said:—

The year 1911 would, he thought, come to be regarded as the beginning of a new era in the history of our country. We prided ourselves as being a great nation, and as such we had many valuable assets, such as our land, Navy, minerals etc., but of all, the most valuable asset of this or any nation was not its ships, nor its land, nor its minerals, but the life of its people. Men could estimate the value of most things, but no one could estimate the value of the life of a single babe. And now in 1911, for the first time in English history, the preservation of that which was most precious to our country was made the outstanding feature in our national budget. He thought he should be excused any party feeling towards this matter, and he thought further that he would be expressing the sentiments of all present when he said that they rejoiced in the fact that at last the health of the people was taking its proper place amongst the great national questions of the day. (Applause.)

Preventable disease was ravaging this country to such

an extent that economists told us the loss to the nation estimated on the basis of manual labour alone amounted to many millions of pounds. The loss of mental work could not be estimated. One disease alone—tuberculosis—was sweeping off thousands of our fellow countrymen and children every year. By it every one in three persons engaged in occupations who died between the ages of 15 and 65 was killed. They had only to attend a meeting of the local Board of Guardians to be struck by the number of applications for relief from the public funds on behalf of widows and orphans of men who had been swept away in the prime of life. Apart from the number which it killed, this disease was reducing thousands yearly from a state of comparative affluence to one of absolute dependency upon the ratepayers. Yet it could be prevented. It would naturally be asked how, and what would the veterinary surgeon do to bring this about.

Well, he read a headline in one of the local papers a week or so ago which at first gave him a bit of a fright, it was "The passing of the horse—Is the veterinary surgeon vanishing." On reading the article he found that there was no immediate cause for them to be alarmed, since it was argued that the horse was a desirable animal to keep, notwithstanding the advent of motor traction. He feared that this interpretation of the work of the veterinary surgeon as simply a doctor of horses was too common, and at once he might say that, important as this work might appear, it was certainly one of the least important of the branches of work committed to the charge of those whose duty it was to study disease as it manifested itself in the domesticated animals. It was now generally conceded by those who took an interest in the subject that the medicine which was of greatest benefit to mankind was preventive rather than curative, and there was little doubt but that during the aptly-termed health age, at the dawn of which they now stand, the efforts of practitioners would be directed on those lines.

Take for instance, again, tuberculosis. It was estimated that 30 per cent. of all adult human beings and cattle were affected by this disease in one form or another. Horses, dogs, pigs, fowl were also affected, but fortunately in lower percentage. The disease was intercommunicable and its existence in the domesticated animals are therefore a source of danger to man. Particularly was this so in regard to cattle, for man was dependent upon this species for two of his most staple food materials—meat and milk. A vigorous onslaught was about to be made on this grave disease. For this onslaught to be successful it was evident that attention must be directed to the disease not only in man but also in the domesticated animals and particularly the cow. This comprehensive view of a disease had been taken in the past with successful results. Rabies, for instance, had been driven out of our country by dealing with the human and canine species.

Now, who was to do this particular branch of preventive work. With all due respect to their estimable colleagues the engineers, into whose profession pessimists sometimes told them to transfer themselves, he did not think the public would feel quite safe in committing the vast branch of comparative medicine to which he alluded to their charge. No, so far from stating that their work was diminishing, it was his conviction that the real work of the V.S. was only now commencing, and that the public was just beginning to appreciate its value to man. (Hear, hear). Then reference had been made that the number of veterinary practitioners were decreasing. That was so. Yet, whilst other branches of science were crowded with research workers amply supported, there was a vast territory of virgin soil, with great problems awaiting solution for the benefit of mankind—a territory in which the workers were altogether

too few, and they could not be expected to produce results on the meagre support which they received.

There were some who appreciated the importance of this question. There were some who recognised the economic problem which inevitably arose if the members in a profession were allowed to decrease at a time when the public demands on that profession were increasing. They were pleased to welcome them there that night. They were pleased that night, as they were always pleased, to receive the sympathy and support of members of their sister profession. Above all, they were pleased that amongst the guests who had honoured them with their presence, was a Member of Parliament who made agricultural research in this country the main point in his maiden speech in the House of Commons, which was a speech in which a man had much at stake. He would ask them to rise and drink with him the health of their guests, and with this toast it was his great privilege to associate the name of Mr. E. T. John, M.P., a gentleman whose breadth of conception has made his name a household word in the great industrial centres of the North of England. (Applause).

Mr. JOHN, in acknowledging the toast, remarked that there was no very good reason why he would be there that night except that he had pleasure to count amongst his constituents their distinguished chairman. He thought it was to that happy fortune that he was present, and not to any knowledge of or connection that he had in any way with agriculture. However, there was this appropriateness in his being there that he did, in connection with the business with which he had been identified from his boyhood, appreciate very highly the value of technical knowledge and skill. Within the last few weeks a very capable, well informed publicist had complained of the lack of expansion of the iron and steel trade in connection with Great Britain. Some eminent and distinguished colleague of his (Mr. John's) in the business had replied that the lack of expansion was inevitable, owing really to insuperable natural difficulties. He was bound to confess there was a great deal of substance in the contention, but his own judgment was that the lack of expansion which had existed for 10 or 15 years was very largely owing to the necessity for technical education and technical knowledge and equipment, and in the second place to an exaggerated individualism, unwillingness and unreadiness, on the part of very capable men who conduct any great industry to pool their common knowledge and experience. It was a very admirable defect in many ways, and was to be found just as prominently in the conduct of a great industry like iron and steel trade as in the humbler one of tenant farming. Men naturally thought of the iron and steel trade as one of first importance, but what had impressed him very greatly was the enormous magnitude of the agricultural interests of this country—and if they would by the side of it that which was represented and cared for by their profession. Quite recently he came across a statement that the sheep breeding industry in Great Britain actually represented no less than 40 million pounds—a staggering figure, and he saw that the entire live stock of the country probably amounted in value to 180 million pounds. In fact, some years ago he noted, it was valued at 251 million pounds. Those enormous figures justified their profession taking a higher status than it at present occupied in the public mind. The meat, dead and alive, which came into the country amounted in value to close upon 40 millions of money. In addition to the financial importance of the subject, one had to recognise the responsibility to exaggerate the importance of the purity of our food and milk and the necessity of sound meat. In addition, there was always connected with agriculture the fact that the population which gained its daily bread by agricultural operations existed under conditions that were peculiarly favourable

to physical and, he believed, moral and spiritual growth. There could be little question that the conditions which surround rural life were more favourable to the development of mankind in every sense than the much less desirable conditions which exist in our great towns. He had been pressing, as had been referred to by the chairman, to the necessity for greater grants—or greater financial assistance—to the development of agriculture. He occupied a position a little different to that of traditional Liberalism, though he did not say that it was different to that position occupied by a great number of Liberals to-day. The traditional position was that it was desirable and proper to leave trade to take care of itself—a policy of non-interference, of letting well alone. He recognised on the other hand there were a great many things which a State could properly do for commerce, and which were absolutely impracticable to private individual enterprise. (Applause.) In Liverpool they were advocating and carrying forward successfully, he understood, the development of this principle in stimulating the production of cotton within the limits of the Empire. That did not directly affect the iron works of the North or agriculture, but he did not grudge in any way whatever contributions the country made to such an admirable project, and in the same way he approved heartily of whatever revenue and assistance the Government extended to the development of agriculture. The broad principle he took in the matter was that wherever the effect of Parliamentary interference was to stimulate production and cheapen the cost he was with them. He was afraid that where the effect was the reverse he was just as strenuously opposed to them.

What was the position, then, of Great Britain in this matter of assisting materially the development of agriculture? He found that the contributions of Great Britain were ludicrously inadequate, compared with many other European countries. The example of Germany was frequently quoted in all sorts of connections. Germany spent on the development of Agriculture no less a sum than £2,710,000, or £20 per 1,000 acres, Little Denmark spent £283,000 which was £40 per 1,000 acres; but Great Britain only spent £183,000 which was a fifteenth part of what Germany spent, and was only 47/- per 1,000 acres. The case for a more liberal treatment of agriculture had been clearly established. In addition to the financial conditions there were the very vital considerations of health. Of the question of the inter-relationship and inter-communicability of disease from animals to human beings it was impossible to exaggerate the importance. He supposed the prevalence of Tuberculosis amongst animals had a close relationship to the wider-spread existence of the ailment amongst the people. He rather gathered that the veterinary profession had during the last 10 or 15 years, or perhaps less, been conspicuously successful in dealing with animal diseases. Lord Carrington the other day said that the Board of Agriculture had succeeded in stamping out almost all the serious diseases of animals. Under those conditions, their occupation, like that of Othello, would soon be gone. (Laughter.) When they remembered the multiplicity and complexity of the ills to which bovine flesh appeared to be heir to they might very well take courage, and look forward with confidence to the future, in which there would be scope for their energies and abilities. Apparently a good deal of success was attending the efforts of the Board of Agriculture and their profession. He saw that the cases of anthrax, glanders and scab now numbered 1,062, in 1910 they were 1,592, in 1909 2,313, and in 1908 2514. So that to-day there were only 40 per cent. of what they were in 1908. On the other hand he found that they were not so fortunate in dealing with swine fever. The Board of Agriculture and the profession generally had been contending this conflict for a matter of 18 years without achieving much success. He believed that this present

year it was almost double what it was last year. In this connection he was pleased to notice that in a reassuring article upon tuberculosis in cattle, it was authoritatively stated that calves were practically free from tuberculosis. That was result which the profession had obtained, and it was very reassuring to humanity. The line he had taken mainly in this matter was to have regard to the interests of agriculture generally. He had been very anxious that everything possible should be done to increase the productivity of the land and to recognise very fully the magnitude of their part in this great industry.

He was sure they would approve of the important step taken by the United States. They were going to spend £137,000 on the inspection and guaranteeing of animals, £52,000 on the eradication of one disease of cattle alone, £16,400 on investigations in connection with animal diseases, £10,400 on co-operative experiments in breeding and feeding, and £9,900 on animal husbandry. One felt it difficult to ascertain from the Board of Agriculture exactly what they spent on research work. He had seen it stated at the very modest figure of some £600 to £900, and he thought the smaller figure was the later one.

He had had some little adventure with the Board of Agriculture himself. (Laughter.) He got some of the information he wanted, but they were unable to tell him what had been spent in America—he supposed because America was too great and too remote—they were unable to tell him what was spent upon Wales, because Wales he supposed was too small and too near. (Laughter.) However he was not singular in his inability to extract information from the Board of Agriculture. Mr. Bridgeman, on Tuesday night asked this very illuminating question, How much was spent last year out of the exchequer upon agriculture, and what proportion out of the amount was spent on salaries and officials in research and on development respectively, and how much was credited to small holdings, and the total amount spent by the State on agriculture in France, Germany, and Denmark? Mr. Lloyd George replied: I fear it would hardly be possible to determine accurately amongst many categories in national expenditure connected more or less directly with agriculture what items can be classed specifically as expenditure on agriculture. (Laughter.) That condition of things was most intolerable. That was to a very great degree characteristic of the department, they not only had a difficulty in extracting money from, but also an equal difficulty in extracting reliable and accurate information. In concluding, Mr. John said he was very glad to hear in regard to their school that they had a practical examination, and he had no doubt that this centre of Veterinary Science would accomplish very admirable work. He was quite satisfied that if Government could be induced to place greater resources at their disposal very excellent results would be achieved. (Applause.)

THE YORKSHIRE VETERINARY MEDICAL SOCIETY.

The Spring meeting was held at the Hotel Metropole, Leeds, on Friday, April 28th. The President, Mr. J. W. Lazenby, Tadcaster, presided, and amongst those present were Messrs. A. W. Mason, Samuel Wharam, Geo. C. Barber, William Crawford, H. G. Bowes, Leeds; G. E. Sampson, A. W. Noel Pillers, Sheffield; F. W. Pawlett, York; F. Hallilay, Dewsbury; M. Robinson, Barnsley; P. Deighton, Selby; Arthur Ellison, Harrogate; A. McCarmick, Hon. Treas., and J. Clarkson, Hon. Sec.

The minutes of the previous meeting, as published in *The Record*, were adopted, on the proposition of Mr. Pillers, seconded by Mr. Wharam.

Apologies for non-attendance had been received from Mr. J. A. Dixon and Mr. Schofield.

The question of subscribing to the Royal Sanitary Institute was raised. Mr. Bowes pointed out that if they intended sending a delegate to the forthcoming Congress it would be a matter of considerable expense, and the question to be considered was whether it was worth the expenditure.

Mr. WHARAM favoured the withholding of the Subscription. It was simply throwing money away, to pay it.

Mr. MASON proposed that the matter be left to the President and the Secretary to use their discretion as to joining or not.

Mr. BOWES seconded the resolution, which was carried.

The SECRETARY alluded to correspondence received in reference to the amalgamation of the Yorkshire Society with the Lancashire and Eastern Counties Societies, in regard to the coming election of the Council of the Royal College of Veterinary Surgeons. Prof. Williams had suggested they should communicate with the North Wales Society and invite them to come into the amalgamation. The North Wales Society seemed to be inclined to join with them, but were enquiring what the cost would be. The Yorkshire Society appointed a deputation to visit the Lancashire Society on the matter. However, the whole matter had now been disposed of, the Midland Society having decided the matter for themselves.

MR. PRATT'S COLLECTION.

Mr. CLARKSON said the members would remember that at their last meeting it was decided (subject to the approval of Mr. Pratt) to give the Council power to place a case, suitable for the reception of Mr. Pratt's valuable collection of horse shoes, in their General Meeting Room, in the Hotel Metropole. To this course of action Mr. Pratt was agreeable, and the management of the Hotel had acceded to their request. Mr. Pratt had expressed the wish that his collection might be taken care of, and that if the Yorkshire Society tired of the collection that it should be sent to some Veterinary College Museum. To these wishes the Council were agreeable.

Mr. WHARAM moved a resolution to the effect that the action of the Council in the matter be confirmed. This was seconded by Mr. Robinson, and agreed to.

With regard to the matter of subscriptions in arrear, the response made to the Council's application—that they should be cleared off—had been particular favourable.

Two names had been struck off the list of members. No nominations for membership had been received since their last meeting.

The resignation of Mr. J. Smith, was accepted with regret, on the proposition of Mr. Wharam, seconded by Mr. Bowes.

PROPOSED KING EDWARD VII MEMORIAL FUND.

A letter had been received by the Secretary from Mr. Shipley, of Great Yarmouth, with regard to this matter. The suggestion was that a Fund be formed, similarly as in the case of the Queen Victoria Memorial. The suggestion is that a fund be formed to provide sufficient money for a pension to one veterinary surgeon, and it was hoped that when Prof. Axe's money was at liberty a house would be provided for the pensioner as well. It was, said the Secretary, for the Yorkshire Society to decide what they would do in the matter.

Mr. MASON regarded this as a time when they might be able to do something. They knew that sooner or later the funds of the late Prof. Axe came in, and he suggested they send a donation from their Society to help the funds of the late Prof. Axe's legacy. He, Mr. Mason, proposed the sum of £5 5s. should be given to the Memorial Fund.

Asked as to the views of the Yorkshire Society's Council in the matter, Mr. Clarkson, said the Council were of the opinion that there would be a considerable

amount of difficulty in raising the necessary sum for a pension. It would mean an expenditure of £700 or £800. He personally feared that the amount necessary for anything like a decent pension was more than the profession could raise.

Mr. MASON explained that his idea was that the subscription from their Society and other Societies should be tacked on to the head funds. By this means they would perhaps be able to get together a decent amount of money.

Mr. CLARKSON said the view of the Yorkshire Council had been that it would be wise to leave the matter over until they knew what others were doing.

Mr. MASON replied that in that case he would withdraw his proposition.

Mr. WHARAM thought the question was as to whether the Memorial Fund would go through. He would like to see the Fund started with a larger sum than £5 5s.

Mr. BOWES was certain that all approved of the principle of the Memorial.

Mr. WHARAM pointed out that their existing Benevolent Institutions seemed to be so constituted that the various Institutions were not spending their money. They were simply piling it up. He welcomed any amount of money being raised for benevolent purposes for veterinary surgeons who were in need of it, but whether in the face of existing Benevolent Institutions not spending their money at present, they could raise a sufficient amount for a worthy King Edward VII. Memorial Fund he very much doubted. At the same time he was sure their Society would join with any other Society in supporting any laudable object for the purpose.

Mr. BOWES proposed, Mr. SAMPSON seconded: "That this Society heartily approves of the principle of the suggested King Edward Memorial Fund, but defers discussion on the matter until a further meeting."

The resolution was carried unanimously.

With regard to the amended rules proposed by the Committee of the National Veterinary Association, Mr. CLARKSON said the matter of these rules had been under consideration for a considerable time. The first draft was sent out some year and a half ago. The draft was amended at a meeting held in Manchester, and re-amended at a meeting held in Crewe. The scheme was then submitted to the different Societies, each of whom amended it, and the general scheme was then submitted to a Committee. The Committee sorted out the various points, and drew up a scheme to be presented to the National Association, who, on financial grounds, threw it out. Another Committee was then appointed by the National Association to consider the question of the rules, and this Committee was particularly anxious for an expression of opinion from the various Societies. Up to the present the Societies in the country had received the matter extremely well. The rules which had been altered were not numerous. Mr. Clarkson then detailed the various alterations suggested. The Yorkshire Council thought it would be wise not to make many amendments to the scheme, but to approve the scheme generally. If alterations were afterwards necessary they could be made by the National Association.

Mr. BOWES proposed that the amended rules suggested by the Committee of the National Veterinary Association be approved of. In dealing with the rules, Mr. Bowes pointed out that from the beginning it had been recognised that the crucial point was the financial question. It was impossible for Societies whose subscriptions were small to pay a large sum to the "National" for affiliation, and therefore it had been suggested that a nominal sum should be charged each member of the different societies affiliated. With regard to the proposed new title of the National Association, he did not much mind it. He knew there was some objection to

the term "Medical" being used, but it was suggested owing to the strong recommendation of the Irish Societies. Their Irish *contrères* obtained their exemption from serving on juries purely on the ground that they were medical practitioners. England was not so well provided for as Ireland or Scotland. Perhaps in time English veterinary surgeons would be afforded this privilege.

Mr. WHARAM did not see any harm in passing the rules as they had been presented to them. He seconded the proposition of Mr. Bowes. With regard to the name of the "National," he (Mr. Wharam) did not care for double barrelled names. They might just as easily put "Surgical" in the place of "Medical" and call it "Veterinary Surgical Society" or anything else. At the same time if it was an advantage to Ireland or to their profession in any part of the country to call it the National "Medical" he did not see any harm in it. He believed medical men in this country received a rebate on the Petrol Tax, and perhaps in time veterinary surgeons would receive it too. With regard to the financial part of the "National" scheme it seemed to have been carefully thought out. It would be well to get the opinion of the "profession" of the country as quickly as possible on the proposed "amended rules," and have the matter settled.

Mr. MASON enquired whether the hopes of the profession was that the proposed amended rules and alterations would increase the powers of the National Society on the lines of the British Medical Society, and bind the members in unity and compel each individual to accept his responsibility as a professional man, on the lines of the British Medical Council.

The SECRETARY replied that was the hope.

The proposition that the amended rules proposed by the Committee of the National Veterinary Association be agreed to was adopted.

SUMMER OUTING.

A suggestion had been made that the Yorkshire Society should invite the members of the Lancashire Society to join with them in a summer outing.

Mr. Bowes moved that Mr. Clarkson, their Secretary, be instructed to write to the Secretary of the Lancashire Society, and if the Lancashire members were agreeable to such an outing to arrange a suitable date and place. The second week in July might be suggested, and Clapham or the Dukeries the place proposed.

Mr. MASON seconded the resolution, which was carried.

SPECIMENS AND CASES.

Mr. WHARAM exhibited specimens of fractured navicular bone, and the hock bones of a Clydesdale mare.

No. 1. Grey Shire mare, about nine years old, 17 hands high.

History. Went lame on near fore, out at work on March 28. The animal had been working in town and the railway yards. Both fore feet were shod with leather. The shoe was removed by the foreman. A wound was found, and the foot poulticed, no nail or anything was taken out of the foot, but the leather which was soft had a corresponding hole in it to the wound.

Seen on 30th, very lame, swelled round the coronet, and up the leg to the knee, wound on sole in the direction of navicular bursa discharging blood-stained synovia.

Treatment. Discontinued the poultices. Dressed the wound with dry dressing. The swelling increased and burst inside the heel. The mare was slaughtered and the fracture found as shown.

No. 2. Bay Clydesdale mare, about 11 or 12 years old, in good condition, never been lame.

History. Went lame on April 1st whilst at work in four-wheeled waggon. Examined by me on the same day. Went on the toe, the hock was very slightly swelled. No particular pain in any part. Had shoe re-

moved and examined foot, saw her next day (she did not lie down during the night) found hock larger, lameness increased. No sign or history of any external injury. The mare was put into slings and the treatment consisted of anti-flam applications, blister, lead lotion, hot and cold water as indicated.

The hock in spite of all burst on the inside, and she was slaughtered on April 24th. I have not seen the bones until to-day they have been sent on to the hotel. I see the articular cartilage is removed in many places, but the true hock joint appears to be all right.

Mr. Bowes said he was particularly interested in the hock case. It was such a case as one got occasionally, and his experience was that one was never sure what the cause was. He had had a number of cases at comparatively rare intervals, but he had never been able to ascribe the cause of the inflamed hock. They got an intensely inflamed hock, very swollen, and the cases were generally most unsatisfactory. He thought that probably they were what would be described as a sprung hock. There seemed to be an inflammation of the joint. In course of time there was a burst out. He thought the only success he had had in cases of that kind had been with the slinging straight away, and perhaps in the early stages applying palliatives, but generally finishing up by blistering. There was one thing, and that was if the cartilages got lacerated there was, he thought, no chance. It would be interesting to know what the cause was.

Mr. PILLERS was interested in the first case mentioned by Mr. Wharam, because it was associated with railway yards. One might perhaps blame the owner for having a horse shod with leather. If there was anything that predisposed to picking up scrap and getting anything in it was leather. The leathers were nearer the ground, and the nails got on it, and were ready at some future date to be jammed into the foot. He thought himself that leathers were most objectionable, and some of the big people who had a lot of horses in places like Sheffield, where horses often picked up nails, had adopted the plan of having a piece of leather with a steel plate on the top of it relaid to the horse's foot. That worked very well, although there might be some objections to it. When horse-owners lost a lot of working time, had to bear the cost of drugs, and run the risk of losing horses, picking up nails became a very serious matter.

BIER'S TREATMENT.

Mr. G. E. SAMPSON: Mr. President and gentlemen, I wish to bring before your notice a treatment which is not so widely employed in our profession as I think the results obtained warrant. I refer to Bier's hyperæmic treatment of injuries to the distal extremities of the limbs. The treatment consists of limiting the venous outflow from the bottom of the limb upwards, and is brought about by the application of an elastic bandage of the Esmarch's type above the seat of injury, preferably below the knee or hock.

Case I.—A bay cart gelding, eight years old, was reported to have picked up a piece of scrap steel in the near fore foot, about the end of January of the present year. I was called to the horse on February 6th and found a punctured wound on the outer aspect at the middle third of the frog, this had already been pared out and poulticed in the interval. I swabbed out the wound with pure carbolic acid, and ordered antiseptic baths, etc.

On February 17th the horse was walking sound, the shoe was put on for exercise. Two days later great lameness appeared, accompanied by a profuse flow of synovia from the wound, there was great pain in the foot, the horse continually scraping with it. Temp. 104 F., and loss of appetite.

The shoe was again removed, and antiseptic baths

with dry dressings afterwards applied. These symptoms—and a variety of dressings—were continued until March 5th, when the case was apparently hopeless, there being still a profuse discharge of synovia which had also burst out in the heel, the horse was unable to extend the limb, dragging the toe along the ground and exposing the solar surface of the foot to view the whole time. On discussing the case with a friend I decided to try Bier's treatment, applying the bandage below the knee for half an hour twice daily. At first there was no apparent improvement, but by March 16th there was evident signs of a better state of affairs; the discharge was less and the febrile symptoms were abating. From now onwards the case made slow but satisfactory progress, a shoe with a hooked toe having been put on, and I have no doubt that in the course of a couple of weeks the horse will be fit to go out to grass. The diagnosis of the case was not absolutely defined, viz., whether the tendon sheath, the joint, or both were involved, but the discharge was certainly synovia.

Case II.—A six-year-old mare of the black funeral worker type, picked up a wire nail in the near hind foot on February 23rd last. I was called in on March 8th, the owner and shoeing smith having treated it in the meantime. There was great lameness accompanied by febrile symptoms, and a punctured wound on the outer aspect of the middle third of the frog. I at once adopted Bier's treatment combined with antiseptic baths and dry dressings.

On March 17th the discharge, which was at first considerable and suspicious of synovia, had ceased, and the mare walked nearly sound.

March 23rd. Shoe nailed on and the mare resumed work in a few days.

Case III.—An aged brown cart gelding, working in a steel dray, was shown up for treatment on December 19th, 1910, very lame from a quarter sanderack on the outside of the off-fore foot.

The usual treatment was adopted, and on about December 25th I removed two bony "sloughs" from the wing of the pedal bone. The lameness gradually diminished, but there remained a purulent discharge which I was unable to overcome, even after twice having cut down on the sensitive structures to search for further necrosed tissues.

On March 13th Bier's treatment was applied, and to-day the discharge has quite ceased, the wall of the hoof is growing down in a sound condition, and the horse is ready for work.

I hope to hear from some gentlemen present their experience with this treatment, so that if their cases have been successful we may adopt the treatment generally, with great advantage to us as a profession.

Mr Bowes enquired whether Mr. Sampson increased the length of the time the bandage was applied, or whether he kept it on the same amount of time, or did he start with a short time and increase it.

Mr. SAMPSON replied that he continued it half an hour at each end of the day.

Mr. Bowes said he had had no experience of this method of treatment. A friend of his had told him of a remarkable success he had had with this treatment. He had a hunter with a very badly inflamed knee. The hunter had struck the knee, or got a thorn in it. He was lame and in great pain. It was not a case of synovia. He applied a bandage, and gradually increased the length of time. His friend did not use an elastic bandage, but an elastic cord. The application was increased a little bit longer each day. The effect in that case was very remarkable. The improvement started almost immediately. After the first day or two the hunter improved all the way, and the animal got quite right. He had often intended to try the treatment. The possibilities were very great.

Mr. CLARKSON said he was glad to hear of Mr. Sampson's success with this treatment. He had had much the same history in one or two cases with pit ponies. He would like to ask Mr. Sampson what kind of bandage he used. The one he (Mr. Clarkson) used was an ordinary human elastic perforated.

Mr. SAMPSON: It was the same thickness as the ordinary elastic garter, and about the same strength.

Mr. CLARKSON said his was a pure rubber one perforated like the one used in human practice for the ankle. He thought without a doubt that each case he had used it on had improved much more rapidly than those without.

Mr. PILLERS (Sheffield) thought from the remarks made by Mr. Sampson, he, Mr. Sampson, could give them a very good paper on the subject. He, Mr. Pillers, had tried the treatment mentioned in several cases, and found it to work well.

The SECRETARY mentioned a case which had recently come under his notice. It was that of a young filly, some three years old. The owners noticed that the filly appeared to be very dazed, and wondered what was the matter with the animal. They called him in. He found the filly distinctly dazed. It was leaning against a wall, and was in very poor condition. He found a distinct enlargement on the forehead. After examination he advised that the animal should be slaughtered. He had brought the head to them for their inspection. He, Mr. Clarkson, thought there was some malignant disease present in the filly.

The CHAIRMAN moved a resolution of thanks to Messrs. Wharam, Sampson, and Clarkson for the cases they had presented to them. They had been most interesting ones.

Mr. Bowes seconded the motion. He thought that from a meeting like that with a few cases presented before them, one learned often as much as from a long intricate paper.

The motion was carried.

The SECRETARY drew the attention of members to the food for beasts provided nowadays. He was inclined to think the foods that animals were living upon at the present time had changed very materially for the worse. Take for instance the case of meals particularly. He had a case the other evening. He was called in to a beast which was eating perfectly well, and in seven minutes the beast was intensely blown up, the muscles were absolutely rigid, the head standing quite out, the eyes staring. When he got to the beast they were drenching her with gin and ginger. The temperature of the animal was 108° 6', but it rapidly fell. He gave an injection. In the morning the beast was all right apparently, and towards evening she cuddled. He thought it was some form of toxin that did the mischief.

In another case the beast was apparently well up to a certain point, the temperature became high, the muscles rigid, but in this case the attack did not pass off as the other did. He, Mr. Clarkson, took it that the food was largely to blame.

They met with diseases in pigs nowadays which he was convinced they did not meet with formerly. Whether it was from the adulteration of food or not was perhaps matter of speculation, but he was very much inclined to blame the putting meal and sharps together. What the constitution of sharps was at the present moment he did not know. He would like to know if other members had had similar cases. He was absolutely convinced the foods were adulterated nowadays.

Mr. SAMPSON said he came across the same thing frequently. He had found in the cases that came under his observation that if they did not kill the animals, they very soon died. A most peculiar thing about the post-mortem was the funny smell. A smell was a difficult thing to describe, but he found in all these cases the same kind of smell.

Mr. CLARKSON remarked that a bad colour was traced. He took it it was a species of toxin.

Mr. SAMPSON: Poisonous seeds in the cakes, perhaps.

Mr. ROBINSON had had one similar case. The temperature was $108\frac{1}{2}^{\circ}$ F at 4 o'clock in the afternoon. Next morning the temperature fell, and at evening the animal was nicely.

Mr. CLARKSON said in the cases he had referred to the owners were using a mixed feed cake.

Mr. ROBINSON: it was so in the case I refer to.

Mr. WHARAM had had a lot of cases very similar to those mentioned by Mr. Clarkson. He usually had them at this time of the year—not when the animals were out at grass. He did not know what the cause was, but he thought it was due to some specific mould on the roots, when they were getting turnips and mangolds. These got very dirty in the piles. In every instance the animals he referred to had been receiving roots. As soon as the beasts got to grass cases ceased. He had examined the food. In many instances the animals had been fed simply on what had been produced on the farm, no meal and no cake had been used from any other place. That was one of the reasons that led him to think that there must be some specific mould which would possibly produce a poisonous toxin. It was very much like strychnine poisoning—the animals affected often lost consciousness, and there was a stiffening of the muscles, but perhaps more like an epileptic seizure than anything else. At any rate, such cases were very difficult to deal with. Owners were always afraid that the animals were going to die. They either recovered quickly, or lingered on, and had eventually to be slaughtered.

Mr. DEIGHTON did not think the soil they ate along with the roots would do much harm. He knew the mould did harm. If the turnips got bitten by a hare or rabbit there was a nasty black place left. He knew if animals ate such bitten turnips bad effects followed. He had known beasts die through eating a small piece of rotten food.

A vote of thanks to the Chairman for presiding, moved by Mr. Bowes, seconded by Mr. McCarmick, brought the meeting to a close.

Tea was afterwards served to the members.

Royal (Dick) Veterinary College.

At a recent meeting of the Board of Management of the Royal (Dick) Veterinary College, Edinburgh, it was intimated that the purchase of a site for new College buildings had been concluded. The site, extending to about one and a half acres, is on the east side of the Meadows, and within easy reach of the University. The cost of the new buildings, which will be commenced without undue delay, is estimated at £50,000.

The Diseases of Sheep.

To the Editor of The Times.

Sir,—Mr. G. Fyde Rowley's letter has caused a good deal of interest to agriculturists, especially in sheep-breeding districts. His opinion as to the great loss of sheep in Huntingdonshire being caused by worms is contradicted by Dr. John Harley in a letter wherein he says, "Worms, live or dead, in the stomachs and intestines, or in either alone, do little or no harm to their hosts—witness bots in the simple stomach of the horse and tapeworms in the intestines of the dog." I wonder where Dr. Harley gained this information? Evidently

not from available literature, because he would there find it stated that bots are not worms; they are the larvæ of the *æstrus equi*, the gadfly of the horse. Evidently not from practical experience, because any owner of dogs can tell him that tapeworms are far from being the harmless creatures that he represents. Is Dr. Harley prepared to state that the *strongylus armatus* and *strongylus tetracanthus* (red worm) found in the intestines of the horse are harmless? In his second letter Dr. Harley has become hopelessly mixed in cause and effect, and his want of knowledge of the habitat of the different entozoa, their life history, and the losses they cause to owners of animals is surprising. Just to mention one or two points in the letter, I have never heard of flukes or tapeworms being found in the heart or lungs. Flukes are found in the liver, not from being "arrested" by accident but because it is their habitat. The same may be said of the *cœnurus cerebralis*, the hydatid causing "gid" or "sturdy" in sheep, and is the encysted larva of the *taenia cœnurus*, and attains its mature form as a tapeworm in the intestines of the dog. It is news to me "that there is no disease of man that is not found in sheep and *vice versa*." There are other points I could touch upon, but I think I have quoted sufficient to prove that Dr. Harley's letter is "contrary to knowledge and misleading."

There can be no mistake about the ravages caused by the *strongylus contortus* found in the fourth stomach in Mr. Rowley's sheep. Any one with a practical knowledge of sheep-breeding will tell you the symptoms—viz., irregular appetite, debility, emaciation, anaemia and death. As a result of the anaemia we very often get effusion in various localities, as in the pericardial sac, which often hastens death. These symptoms plainly indicate that the very life of the animal has been sucked by these pests. There cannot be any other cause. The sheep had been well cared for and well fed. Directly these parasites are destroyed the animal feeds better, gets stronger, and thrives even to the extent of getting fat. The importance of an early diagnosis to eradicate worms in sheep or lambs cannot be urged too strongly. The early autumn is a good time to tackle this trouble, as it is at this time of the year so many of these parasites find their way to their hosts. The different anthelmintics employed are frequently disappointing, and when the worms are numerous and well-established in the stomach and intestines it is difficult to dislodge them. In my opinion this widespread trouble is due to the past two wet summers. Worms can only live for a limited time without moisture. In lambs just now worms of various sorts are very common and causing great anxiety. The *trichocephalus affinis* or hair-necked worm is very prevalent in the large intestines, causing persistent diarrhoea, weakness, and death. This worm is very often accompanied by other worms, a small *strongylus* in the fourth stomach, and even by the *strongylus filaria* found in the air passages, causing hoove. The advantages I found in using the capsules mentioned in Mr. Rowley's letter were—(1) Easily and quickly administered; (2) the medicine being given in a concentrated form gave a much better result than any liquid vermifuge in the form of a drench; (3) the dose of the medicine in the capsule can be largely increased beyond the ordinary dose, which is a very important point.

In conclusion you might ask what I recommend as a preventive. Early administration of medicine and the ploughing up of pastures infested with these worms where practicable.—I am, sir, yours obediently,

CLEMENT BURSTON, M.R.C.V.S.

* As Diseased or Exposed to Infection

The Outbreak of Glanders at the Collieries of the Ebbw Vale Co.

A report has been issued by Mr. J. S. Martin, I.S.O., (late Inspector of Mines for the Southern District), and Mr. D. Rocyn Jones, M.B., D.P.H., (County Medical Officer for Monmouthshire) on an investigation they conducted relative to an outbreak of glanders among horses, and the alleged general insanitary condition of the collieries, belonging to the Ebbw Vale Steel, Iron and Coal Company, Limited.

They explain how the enquiry originated through a statement made by Dr. Davies, Medical Officer of Health for the Ebbw Vale Urban District Council, at an inquest held at Beaufort on November 8, 1909, upon a haulier, named John O'Shea, who was employed at the Ebbw Vale Steel, Iron, and Coal Company's Waunllwyd Colliery, that death resulted from blood poisoning having the appearance of "Farcy," and that he had known of a number of workmen engaged in this Company's collieries die from causes due apparently to the insanitary condition of their employment: this statement being followed by a question asked in the House of Commons by Mr. T. Richards, M.P. This resulted in the Home Office requesting Messrs. Martin and Jones to make a thorough investigation into the sanitary condition of this Company's mines.

Accordingly they made a series of visits to the Company's mines, accompanied by Mr. C. L. Robinson (Assistant Inspector of Mines), Dr. T. W. Wade (Assistant Medical Officer to the Monmouthshire County Council), and Mr. D. M. Storrar (Fellow of the Royal College of Veterinary Surgeons and Veterinary Inspector to the Monmouthshire County Council), besides the colliery officials, and made a personal inspection and enquiry above and below ground.

After detailing the sanitary conditions prevailing at the various Colliery workings on the dates of inspection, the Reporters state that during their visit of inspection the stables underground were in each case inspected, and their condition from the standpoints of general sanitation and the possibility of conveying infection from defective structure or unwise practices were carefully investigated. The stables were in good order, but since this inspection they have been thoroughly overhauled, some being replaced by new ones in order to eradicate any likelihood of infection in the future. As the result of their inspection, the Reporters were pleased with the general sanitation and cleanliness of the stables, and although they were not in all cases ideal, yet very little condemnation could be passed upon them.

Mr. Storrar was told off to investigate the general condition of the horses, with special reference to the presence of glanders amongst them, and on Friday, May 13, 1910, he selected five horses from different pits showing symptoms which, although in no way definite, he considered might be regarded as suspicious, and to these he applied the "Mallein" test with the result that four of them reacted. Upon this result Mr. Storrar was directed to officially report the presence of glanders amongst the Company's horses to the Chief Constable and Chief Inspector for the County of Monmouth, under the Diseases of Animals Act.

A general test of the whole of the colliery horses was decided upon, and to interfere as little as possible with the working of the Collieries and consequent distress in the district, such was carried out at the week-ends in batches, the result of which was that the testing has been much prolonged and this report delayed.

The result of the "Mallein" test has been such as to reveal a very serious state of affairs, which could not be determined by ordinary examination, as in very few

cases, indeed, could there be found any external symptom definitely indicating the disease. It also showed that however well kept a stable may be, if a horse affected with glanders is introduced into a stud, either over or underground, there is very great risk of the whole stud ultimately becoming affected. The total number of horses inoculated, including those of Mr. Thomas, contractor, at Victoria Colliery, was 319, and out of this number no less than 133 reacted to the "Mallein" test, giving definite evidence of being glandered, all of which have been destroyed. Two pits were entirely free from glanders, viz.:—No. 1 Waunllwyd, containing 57 horses, and the Victoria No. 1 Colliery (Mr. Thomas, contractor), containing 32 horses. All the other stables, over and underground, were affected in varying degrees.

The Ebbw Vale Company have taken precautions to prevent the disease occurring again by having every horse tested with mallein before purchase, also frequent applications of the test so as to pick out any animal that may, in spite of care and all measures, find its way into a stud. Although the stable ventilation and general sanitary conditions are above the average of colliery stables, the Company have in every pit built temporary stalls for new horses that have been introduced, to prevent any possible contamination, and also allow a thorough disinfection of the permanent ones, which have had everything done to them which is possible to destroy all infective germs. Wooden mangers have been replaced by iron ones, new floors laid down, and stall divisions erected, all of which is very essential, but Mr. Storrar points out that the great point must not be forgotten, that is, to keep the disease out by means of the mallein test, as it is the only method of detection when it assumes an occult form, as in this outbreak. One of the greatest causes of the spread of the disease is the careless use of the "nosebag," and the common drinking place. Bad hygienic and insanitary arrangements and overwork will not produce the disease, but they will (more particularly overwork) give a great impetus to the spread of the disease once it finds its way into a stud.

The report then gives the result of the investigation into cases of infectious diseases and blood poisoning alleged to have been contracted amongst workmen employed underground in the Ebbw Vale Urban District through the alleged insanitary conditions of the collieries of the Company, and also of typhoid cases amongst colliers for the period covered by the years 1900-1910.—*The Iron and Coal Trades Review*.

Congress of the Royal Institute of Public Health.

TO BE HELD IN TRINITY COLLEGE, DUBLIN,
15TH TO 21ST AUGUST, 1911.

There are several Sections in which Papers will be discussed of general interest, and in one Section, the Pathological and Veterinary Section, matters of special importance to the profession, will be debated. In addition to the ordinary business of the Congress, there are to be entertainments of different kinds for members, such as garden parties, conversaziones, theatres, etc., all of which will be most enjoyable.

We are very anxious to have a representative gathering of the profession, and we should like to know if you will become a member of the Congress, the fee for which is half a guinea.

A. E. METTAM, President of Section.

A. WATSON, } Secretaries.
E. C. WINTER, }

Members of the Congress are sent a voucher which entitles them to travel for a single fare and a quarter return ticket.

PATHOLOGICAL AND VETERINARY SECTION.

1. President's Address.
2. Diseases communicable from Animals to Man.
Professor Craig, M.A.
3. Suggested amendments in the Laws and Regulations dealing with Milk.
Sir Chas. A. Cameron, C.B.
4. The Relation of Bacilli of the Typho-Coli Group to Meat-Poisoning and Para-Typhoid.
Professor E. J. McWeeney, M.D., M.CH.
5. Contamination of Milk occurring between the Cow and the Consumer.
W. J. B. DeVine, F.R.C.V.S., D.V.S.M.
6. Keeping of Animals and their influence on Public Health.
W. Cargill Patrick, F.R.C.V.S.
7. Meat Inspection in Rural Ireland—What it is and What it ought to be.

P. J. Howard, M.R.C.V.S.

PARLIAMENTARY.

In the House of Commons, on Tuesday, July 4.

FOOT-AND-MOUTH DISEASE.

In reply to Sir H. Verney (Bucks, N., Min.), Sir E. STRACHEY (Somerset, S., Min.) said: I regret to say that foot-and-mouth disease has broken out at Blands Farm, Hounslow, Middlesex. Of the 76 pigs on the farm at least 42 are affected. One heifer out of the 19 cattle is also affected. All these animals, affected and in contact, will be at once slaughtered, and the usual steps for isolating the infected area have been taken.

Personal.

ROBERTSON.—At his residence, Lismore, New South Wales, to the wife of James A. Robertson, a son.

Mr. JAMES H. THOMSON, M.R.C.V.S., Oban, has been appointed Veterinary Inspector for the County of Sutherland.

The Lord Lieutenant has been pleased to appoint Mr. CHARLES ALLEN, F.R.C.V.S., 35 North Frederick Street, Dublin, and Fortmarnock, Co. Dublin, to the Commission of the Peace for the Borough of Dublin.

OBITUARY.

W. O. ROBERTSON, M.R.C.V.S., Ettrick Place, Selkirk.
Graduated, Glas: May, 1892.

Death occurred on June 29th, from meningitis, at the early age of 41 years.

CORRESPONDENCE.

IS IT MEGRIMS, AND IS THERE A REMEDY?

Sir,

Twelve months ago a one-year-old Airedale terrier was treated for distemper. The disease ran an easy course, and recovery was speedy. The only sequel was a slight shaking of the head at infrequent intervals. Lately the head shaking has become a daily occurrence, and is performed with violence, the dog falling in an exhausted state. After a minute he rises and scampers as if nothing had occurred to disturb the serenity of his existence.

His health is excellent, his ears are clean, his teeth are perfect—Yours, etc.,

June 28

WOODFORD.

ANTHRAX IN THE HORSE.

Sir,

I was much interested on reading Mr. Carter's case of anthrax in last week's *Record*. Most of us have been at different times puzzled to account for some outbreaks of anthrax, especially when cases occur singly and are not followed by others. A recent experience of my own may be interesting.

A client of mine found a fat cow dead (or dying) lying by the side of a brook. He had the animal stuck, and a heavy thunderstorm coming on some of the blood was washed into the stream. When dressing the carcass anthrax was suspected and I was sent for. I found the spleen about three times the normal size, and anthrax bacilli in the blood.

The Police at once fenced off and disinfected the place where the animal died, but a week later a horse [which had access to the brook in question died suddenly, and on a microscopical examination I found anthrax bacilli in the blood.

This brook flows for a mile and a half through a grazing district into the Trent, and so on to the Humber. Here seems to me a not unlikely cause for some future mysterious outbreak of anthrax along the banks of this stream.

Another interesting feature of this case is that my client assured me his cats and fowls ate of the cow's carcass without ill-effect, and the butcher when dressing same, repeatedly put his knife between his teeth; beyond a severe fright on learning the nature of the disease, which his friends feared would prove fatal to him, he is, up to now, none the worse.

I may add that both these cases of anthrax were confirmed by the Board of Agriculture.—Faithfully yours,
GEO. WARTNABY.

Burton-on Trent, July 3.

THE CAUSE OF SWINE FEVER.

Sir,

I have now, after several years working in the dark, satisfied myself entirely as to the cause of this disease. It is due to a minute strongyle which burrows into the intestine causing ulceration of the bowels, and a worm in the lungs setting up broncho-pneumonia.

I have often wondered why it has baffled every attempt to eradicate it, and am now satisfied that it is useless to try and do so.—Yours, etc.,

GEO. UPTON.

THE LIMITS OF DIAGNOSIS.

Sir,

So long as our patients are not possessed of the power of speech, so long will our diagnosis of their ailments remain more obscure than in the case of the human subject. The only animal that might have enlightened us as to pain and symptoms when ill would have been Balaam's ass, and unfortunately he is long since dead. It is said that "in much wisdom is much grief, and he that increaseth knowledge increaseth sorrow," and the wider and deeper the diagnostician's knowledge, the more he will appreciate the difficulties in giving an opinion, and the slower he will be in expressing it; but it is no good casting pearls before swine, and the wise practitioner must know his man before he talks much book to him.

Occasionally we meet a worldly-wise, cultured, widely read and educated man, and if we belong to the cocksure crew we cut a sorry figure.

There are two sorts of self-confidence, that of ignorance and that of the man that knows. Unfortunately the first attracts the public by its glamour and assumed omnipotence, but time put the stamp of inefficiency upon it after a period, and the infallible practitioner drops to his true level, whilst his careful and less cocksure contemporary comes by his own and advances in the public esteem.

However it may be in other parts of these Isles, I have found that owners of animals do take some interest in a dead carcass, and if a veterinary surgeon does not attend a post-mortem he is often asked or expected to do so. He would be requested to do so more than he is if his fee for attend-

ing a post-mortem did not come on top of the loss of the animal.

The following story seems to me to illustrate the strength of the argument and the value of the evidence against the non-employment of therapeutic measures, drugs included, and the weight of the inferences sometimes drawn from such cases as recover naturally.

A white man kept a goat, a black man living next door to him complained that the goat smelt. The white man retorted that the black man smelt a jolly sight more, whereupon the black man sued the white man for damages for libel. When the goat was brought into court both judge and jury fainted. Having recovered, the black man was called into court to give his evidence. When he entered the witness box judge, jury, and goat fainted. Result: Verdict for defendant with costs on the higher scale.

The inference that some men might draw from this tale is that all black men or the majority of black men smelt stronger than goats, but the true inference drawn from the story does not warrant any such conclusion.

In out-of-the-way quarters of the world, where coarseness is king and ignorance flourishes, it is always possible to come across the tail shotten, worm in the tail believer, and the cayenne-pepper-giving, onion-to-the-vagina fiend, but these individuals are no great catch as clients, and their conversion to the ranks of the eminently sane would possibly be only accomplished by earthquakes or Gatling guns. As regards money making, I am afraid we must all make as much as we can; most of us have pet ways of trying to make it, differing a bit in degree, but having great similarity in the source and cause of the driving power.—Yours truly,

G. MAYALL.

Sir,

I have read with great interest the article written by Mr. Wallis Hoare on the above subject, and also the reply, if one may so term it, by Mr. G. Mayall.

Now in the first place let me say that I yield to none in my admiration of Mr. Hoare and his articles, and therefore that I am a prejudiced critic right at the beginning. But allowing for my little bias, I think that many of your readers must have agreed with his "dicta."

I am quite a junior of the juniors in our profession, but during the last eight years (four in college and four as a practitioner) I myself have had many salutary lessons showing me the extreme difficulty of arriving at a correct diagnosis in a given case.

My first blatant error happened when, as a particularly green assistant, I was dispatched to report upon a case. After a prolonged examination, lasting nearly an hour, and a badgering of the poor owner with needless questions, I returned with a glowing description of symptoms and diagnosis of "general rheumatism." As I wended my way through the maze of symptoms in relating my experience to my master, to this day his tones ring in my ear as he said "I think it is quite evident that the horse has tetanus. I hope you did not mention anything about rheumatism to Mr. ———." The remembrance also comes to me of another day, in College, when one of our professors pointed out to our admiring gaze a lipoma on the side of a dog's chest. It was only a teat placed slightly out of line!

The above are two instances of mistakes, the one of a junior (*mea culpa*), the other of a learned man high in the ranks of the profession, made simply through thoughtlessness and carelessness.

But there are other mistakes one makes, even after one has left the callow College stage, and when one can claim to approach a case viewing it in all aspects, and adopting towards it both a critical and a deductive philosophy, and it is those mistakes which convince us of the limits of diagnosis.

Some time ago I had occasion to visit a cow which, to my mind, presented all the symptoms and had all the history of that phase of cerebral trouble we term stomach or sleepy staggers. The cow had calved a month previously and had been turned out on a patch of clover for the first time that day. She came up gorged with food, and when I arrived on the scene she was standing in a listless state, head hanging, eye sleepy, pulse sluggish. As I watched,

she had an attack of frenzy and apparently seemed in pain, struck at her abdomen with hind legs, glared round the box, and then proceeded to try to produce a small cyclone on her own.

With conspicuous bravery (?) I handled the case, and having administered the usual purgative and other treatment that seemed to apply, I left the place covered with glory. On the following day I discovered her in about the last stage in milk fever! 'Nuff said. She recovered in about 12 hours, I in about 12 weeks.

I have had the pleasure of meeting those lucky individuals who tell me they have never made a mistake in diagnosis. I usually find that it is indeed true, for they have never made a diagnosis. "A chill (beautiful word) on the liver, stomach, kidney, bowels or back," "lame in the shoulder," "lame in the foot"—such are the brilliant efforts of those delightful individuals who never make a mistake.

With regard to the use of drugs, may I ask this question? Did any of us ever meet a medical man—doctor or veterinary surgeon—who had risen above the line of empiric or quack, and who had the slightest faith in scores of the drugs in his surgery when they were prescribed for himself by his own medical attendant? We must grant the efficacy of a few drugs, the derivatives and compounds of, say, Ammonia, Opium, Nux vomica, Cinchona, and Iodine. But the rest—!

Take a man who is a bit "off colour," he is prescribed for and receives that old favourite a "bitter tonic"—Quassia, Columba, and that ilk. Now is it not a fact that exactly the same effect could be produced by a half-hour's gallop, or some such exercise, or even by a humble "glass of light bitter, Miss," but perhaps your readers may look on a glass of fo'penny as a medicine, like the old Scotch parson. I don't.

Are we to be told that the country practitioner, of whom I am one, when he solemnly hands out his packet of "condition powder" (Mag. sulph. and sulphur flores, with ferri carb. a trace) and such like medicaments, that he for one moment believes that it will do a whit of good. Believe me he doesn't, and he is very careful to instruct his client of both quantity and quality of food to be given, striving to attain by those means the result he wishes to be credited to his nostrum.

If he does not feel that half of his prescribing is, to use Mr. Mayall's Parliamentary phrase, bunkum, he must have a more brilliant imagination than I possess, and he should give up his work and become a compiler of statistics for the use of Free Trade and Tariff Reform lecturers. He would be the "success of the season."

To my mind we must be honest with ourselves, acknowledge our mistakes freely, try to rectify them openly, administer medicine *a placebo* if we must, but try to encourage careful nursing and dietetic methods to bring about those results which will be a credit to ourselves and our profession, and save us from the degradation of becoming empirical know-alls.

With regard to lameness—may I be permitted to give to Mr. Hosre and Mr. Mayall a little tip told me by a fellow student on the celebration of his third failure at the "final." "When a horse is lame, blister all four legs, you will probably hit the right one."

MOMPARA.

THE OBJECTORS TO THE AMENDMENT BILL.

Sir,
I have read in the *Record* of 24th June a letter by J. P. Isherwood, Headed "The Amendment Bill and the Objectors," in which he expresses the opinion that, "The Majority of the Profession are pretty well disgusted at the address to Members of the House of Commons." That address appears in *The Record* of June the 17th, and as a member of the profession I fail to see where disgust comes in. Mr. Isherwood might also be surprised to learn that the "disgust" is not very wide spread, and that the five gentlemen whose names are appended to the address, are only doing duty for a very large number of members in England, Scotland and Ireland, who have all along been dissatisfied with the high handed way in which the Council has dealt with the question from the first, and although the Bill

has been more than once trimmed to get free from the opposition of outsiders (the last being the H. and A. Society). Still it is a delusion to imagine that the members of the veterinary profession can be handled any way, and they will have something to say before the Bill as it stands will become law, and I would simply tell Mr. Isherwood that it is not the objectors to the present Amendment Bill, that aim at "destruction," but a few who simply want their own way. I may also state that other Members of Parliament, than those who introduced the Bill, had their eye on it. I agree with Mr. Isherwood and others that money is required, and I also agree with him that a registration fee of 10/6 should be ample. Further, that no increase of students' fees should be made, there are many other points in the present Amendment Bill that require to be dealt with by the Profession, and not simply by the members of Council—then we might look for "Construction." For instance, the pertinent question has been asked, what is the Council going to do with £3,000 a year? and what benefits are the outside members of the profession likely to get, or what influence are they likely to have. The present method of electing the Council makes it like one of the old close Corporations, where with very few exceptions, the same men are elected year after year, why not make the retiring members be one year out of office before they are eligible for re-election, and break up cliques. This Bill will not be carried without the approval of the general body of the profession, and the simple election of members of Council for general purposes does not give that approval.—I am, etc.,

A. I. McINTOSH.

Dumfries, 26th June, 1911.

Sir,

As one of the signatories to the Appeal to Members of Parliament, I must take great exception to the remarks of your correspondent Mr. Isherwood. We admit that the Royal College is in want of money, but how much and for what purposes the Royal College has not deigned to consult the profession. According to your correspondent's opinion half the annual sum asked would be sufficient. We say, for argument's sake, £1,000 would be ample for present needs, and an appeal to the profession would have met a ready response. We are not "blinding ourselves to facts," but in the face of the decrease in students year by year, the decrease of practice (there is no question that the ordinary practitioner finds it difficult to get a living and can ill afford fresh burdens), we are aware there is decay and depression which threatens to last for a decade.

Vis unita fortior is a very good motto, but I fail to see how the "unita" is to be maintained by coercion, or the "Vis" made "fortior" by the "despicably mean way" of putting a yearly tax on an already heavily handicapped calling.—Yours truly,

HENRY DYER.

Brompton Road. June 28.

Sir,

But that the gross libel of your correspondent "Mephistopheles" affects some 900 members of the profession, I should have treated his letter with the silent contempt that such attacks from the "Devil" deserve. Your space is valuable and I will be brief—in italics, sir, please, as "I think it deserves the distinction."

I have seen some 600 signed letters from opposers of the Bill, these letters with many more are in Mr. Hurdall's possession and can be seen by anyone wishing to know the truth.

I think it unnecessary to comment on other fabrications of "Mephistopheles," and am content to leave judgment in the hands of all honest men, but at the same time, as Englishmen we all have a right to our own opinion, and ought not to be subject to such sneering and scurrilous innuendos as those produced by such an evil mind as "Mephistopheles," who, by the way, has chosen well his *nom-de-plume*, "Not loving the light."—Yours truly,

HENRY DYER.

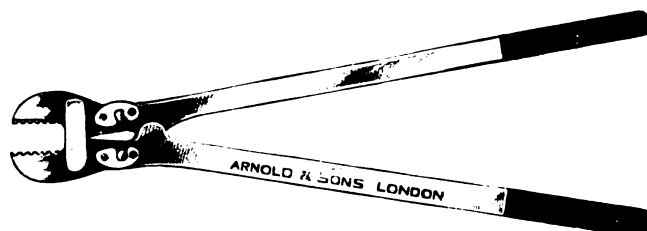

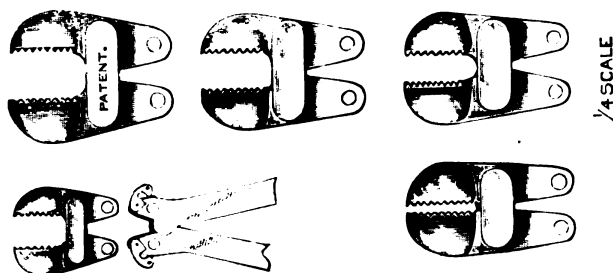

Brompton. July 3.

[A point of importance is the date of the letters, which should be known.—ED.]

Practices for Disposal

DEATH VACANCY. An opportunity of securing an old established country practice has occurred on account of death of principal. Situate in Eastern Counties. Represented as returning considerably over £400 p.a. Good contracts returning £160. Good house and premises at £45 p.a. Hunting in immediate vicinity. Further particulars and introduction only to would-be bona-fide purchasers.

15 MILES OF LONDON. A good-class mixed practice represented as returning about £650 p.a. is for immediate disposal. Capable of considerable increase. Nice and convenient house consisting of 10 rooms. Good stabling, coach-house and dog kennels. Strictest investigation courted. Good introduction will be given. Satisfactory reason for relinquishing. Further particulars on application.

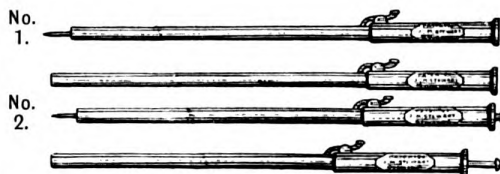

DEATH VACANCY. An old established practice in a London Suburb is for immediate disposal, represented as returning £150. This amount, it is stated, can be easily increased by an energetic Practitioner. Price asked is £100 to include drugs, instruments, kennels etc. Inclusive rental of premises £1 2s. 6d. Further particulars and introduction on application.

SALOP.—We have just had placed in our hands for disposal a well-established Practice represented as returning last year £375. County Council appointments. Good reasons for selling. To an immediate purchaser Vendor will accept an offer of about £250 to include Surgery fittings, drugs, instruments, etc.

C. H. HUISSH & Co.,

12 RED LION SQUARE, W.C.

Patent Balling Gun for Horses and Cattle

This is the best and most practical balling gun yet put in the market. One should last a lifetime. It is also useful in giving pessaries to mares and cows in cases of uterine disorders or retention of the placental membrane. It is impossible to do injury with this gun as the point is perfectly guarded by the ball. The point retracts into the sheath.

Makers have reduced their price,

I now offer either of these guns at 15/- each.

The Glasgow Veterinary College,
INCORPORATED.

Principal: JAMES McCALL, F.R.C.V.S.
Session, 1911-1912.

This College is under the management of a representative Board of Governors and is recognised as a Central Institution under the Education (Scotland) Act, 1908. A complete course of instruction is given in the subjects of examination for the Diploma of the Royal College of Veterinary Surgeons, and the field for clinical observation is unsurpassed. The equipment of the College is being extended and modernised. Students are eligible for bursaries granted by Secondary Education Committees of the Counties and certain Burghs of Scotland.

The Matriculation Examination conducted by the Educational Institute of Scotland for intending Students will be held on 6th, 7th, and 8th July, and 7th, 8th, and 9th September.

Next Session commences on Wednesday, 27th Sep. 1911

Further particulars may be had on application to the Principal, or Alexander Russell, 54 West Nile Street, Glasgow, Secretary.

Royal Counties' V.M.A.

A general meeting of this Association will be held on *Thursday, July 20th.*

It has been decided that, being coronation year, this meeting shall include a River Trip, and arrangements have been made by the committee appointed for that purpose.

Conveyances will meet the 12.33 train from London arriving at Maidenhead 1.28, the train leaving Reading 12.58, arriving at Maidenhead 1.17 and the train leaving Oxford (via Wycombe branch line) 11.20 arriving Maidenhead 1.12. The party will be driven to the Launch "Empress of India" at Boulter's Lock: thence up river to Henley, arriving about 6 p.m. Convenient trains leave Henley at 6.35 and 7.43 for London and Reading. Luncheon and tea will be served on board the Launch: Tickets 12s. each, include conveyance from station, luncheon, tea, and launch.

Any member of the Veterinary Profession and friends will be heartily welcomed. The Committee particularly hope that ladies will be present. *An early application* for tickets, enclosing cheque to the Hon. Sec., is requested, in order that final arrangements may be made.

The meeting for the necessary business will be held in the Saloon during the trip.

G. P. MALE, Hon. Sec.

The Annual Meeting will be held at
CARNARVON,
Wednesday and Thursday, July 26th & 27th
 Annual Banquet on the evening of Wednesday, July 26th.

The Provisional Committee have arranged for the following papers:—

Veterinary Education in Relation to Public Health, Dr. O. C. BRADLEY.
 Discussion opened by J. W. BRITTLEBANK, M.R.C.V.S., D.V.S.M.

Sclerostomiasis, Dr. H. E. ANNETT, M.D., D.P.H., Professor, Dr. LEIPER, M.B., F.Z.S.
 Discussion opened by A. W. NOEL PILLERS, F.R.C.V.S.

Surgical Shoeing, H. SUMNER, M.R.C.V.S.
 Discussion opened by E. A. WEST, F.R.C.V.S.

Principles of Economic Feeding (Horses and Cattle) H. TAYLOR, F.R.C.V.S.
 Discussion opened by HAROLD A. WOODRUFF, M.R.C.V.S., Professor.

DRUGS, INSTRUMENTS, ETC. Those desirous of exhibiting should apply at an early date, stating space required, to—

L. W. WYNN LLOYD, Carnarvon, *Hon. Sec. Provisional Committee.*

Saloform Pessaries.

The New Uterine Antiseptic

Highly recommended by many eminent
 Veterinary Surgeons.

PRICES: Ordinary Strength, White.

4/6 per doz. 48/- per gross.

Extra Strong, Yellow.

6/6 per doz. 72/- per gross.

Sole Proprietors—

HARKNESS, BEAUMONT & CO.,
 Wholesale Chemists,
EDINBURGH.

Veterinary Surgeons have for long keenly felt the want of something which could be used with good results as a Uterine Antiseptic and which at the same time could be quickly and easily administered. After many trials, and with the kind co-operation of some able Veterinary Surgeons of great experience in parturition cases, we have succeeded in producing

a Pessary made with a non-olly base which does its work efficiently and at the same time is non-irritant—in fact, soothing in its effect. They are of great use in parturition in cows or mares; and if administered immediately after parturition they will keep the Uterus clean and healthy, and prevent the after-birth becoming foul.

Veterinary Surgeons in various parts have highly recommended them, and there is an increasing demand for both kinds.

Customers are requested when ordering to state which kind they prefer.

A RECENT UNSOLICITED TESTIMONIAL.

AINSWORTH WILSON, ESQ., F.R.C.V.S., writes:—

"I have used the Saloform Pessaries supplied by Messrs. Harkness, Beaumont & Co., of Edinburgh, with good results in various diseases of the genital organs, both in mares and cows, more especially after parturition. They are particularly useful in retention of the afterbirth, with septic complications. It is often impossible to attend more than once a day to irrigate the uterus; in such cases it is good practice to leave one or two of the "extra strong" pessaries *in situ*. I have found them an excellent substitute for Iodoform and other well known non-irritating antiseptics. I feel justified in recommending them to the profession.

Witham, Essex.

THE VETERINARY RECORD

A Weekly Journal for the Profession.

EDITED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1201.

JULY 15, 1911.

VOL. XXIV.

THE COUNCIL MEETINGS.

Last week's Council proceedings were neither long nor particularly interesting. The first business was the appointment of a President, and the first name proposed was that of Mr. Villar, than whom no worthier occupant of the Chair could have been found. It transpired, however, that Mr. Villar unfortunately was unable to accept office; and the Council then unanimously selected Prof. Mettam as President for the year. It is unnecessary to comment upon an appointment which will commend itself to everyone. We all know the new President's personal attributes and his record of work for the profession within and outside the Council chamber; and we all know what may be expected from him in the Chair.

The College finances present the usual deplorable picture. Every quarter the Treasurer has a mournful little speech to make, but this one makes worse reading than any he has yet delivered. Briefly, the position is this—that, all other resources having failed, £1,000 worth of Consols are now about to be sold, but that the necessity of repaying the bankers' overdraft of £570 from the proceeds of the sale will leave only some £200 in the Treasurer's hands, and that he will probably therefore be obliged next October to ask for authority to sell another £1,000 worth of Consols. It is very possible, therefore, that the last six months of the present year will see one-quarter of our scanty capital sunk to repay debts and meet current expenses—a situation which we may well leave to speak for itself.

One other very important matter was dealt with. The Council have refused to recognise the Veterinary Degree of the University of Melbourne as at present constituted, and the refusal was undoubtedly justified. The sole reason appears to be the constitution of the Veterinary Examining Board of Melbourne University, which is arranged on lines diametrically opposed to ours. Our regulations preclude teachers from acting as examiners; the Melbourne Board, on the other hand, consists exclusively of teachers, and therefore affords no such guaranty of an independent test of the candidates' knowledge as does ours. It is possible, of course, that the authorities at Melbourne may be induced to re-model their regulation—we hope they will. But it was clearly out of the question for the R.C.V.S. to recognise a degree granted upon an examination system so essentially inferior to its own.

THE CARNARVON MEETING.

The National Veterinary Association hold their annual general meeting on July 26th and 27th in the Guildhall, Carnarvon. Nothing need be said of the town or surrounding district except that their attractions have filled columns of the newspapers for some days past. What with the scenery, the historical attractions, and the recent patriotic events it must be confessed that the "National" was happily inspired when it chose Carnarvon for this year's meeting. The four papers to be presented for discussion are all interesting and instructive, besides which it is hoped that, at last, the scheme for affiliating all our Societies may be accepted.

The annual dinner will be held on the evening of the 26th at the Sportsman Hotel.

On the 28th an excursion is offered to Snowdon, with luncheon at Beddgelert, and sufficient time for those who desire to see the view from the top of the mountain to make the ascent by mountain railway.

Members who attend the meeting should write and engage rooms either at the Royal, The Sportsman, Prince of Wales, Castle, or Commercial. Probably the town will not be crowded on the 26th, but so much has been said of the beauties of North Wales that it is safest to engage rooms in advance.

A golf tournament has been arranged, and all who desire to take part should give early notice to the Secretary, Mr. Wynn Lloyd. One more word of advice we may offer—that every member should use the postcard which will be sent, so that the local officers may know how many to expect and be able to arrange accordingly.

THE ROYAL COMMISSION ON TUBERCULOSIS.

"Man must, therefore, be added to the list of animals notably susceptible to bovine tubercle bacilli." This single sentence from the long-deferred Final Report of the Royal Commission may almost be taken as summarising its main moral.

It is satisfactory to note that this lengthy Report is unanimous. It is signed by all five Commissioners (including the late Sir Rubert Boyce), and we expect it to prove the most powerful factor that has yet appeared in awakening the public to the danger arising from tuberculous meat, from tuberculous milk especially, and, perhaps most of all from the tuberculous cow.

FATAL HÆMORRHAGE FOLLOWING TOOTH EXTRACTION.

J. McRAE FROST, M.R.C.V.S., Wimbledon.

Mr. G. H. Livesey's article "Unexplained Hæmorrhage," reported in *The Veterinary Record* of June 17th, recalls to my mind a case I had about two years ago, which may prove of some interest, as cases of the kind appear to be rare in canine practice.

The subject, a Scottish terrier, four or five years of age, was brought to me for advice concerning a permanent discharge coming from below the orbit. This was diagnosed as pus in the antrum of the carnassial molar, and extraction of that tooth advised. I performed the operation under chloroform, the tooth coming away without difficulty, passed a probe from the facial outlet to the socket of the tooth and syringed through with chinosol. Hæmorrhage was no more pronounced than one usually meets with in extraction of this tooth, and the owner took the dog home at four o'clock—three hours after the operation everything apparently satisfactory. As a rule in these cases I give an antiseptic to be syringed through for a few days (as I did in this one) and think no more about them. However, on the morning following the operation I had a telephone message to call and see the dog as soon as possible as it had lost a good deal of blood during the night and was bleeding freely at the time. A hospital nurse had meanwhile done what she could for the patient in the way of syringing the socket with ice-cold water, plugging etc., but without avail. On arrival I syringed with a solution of adrenalin until bleeding ceased, and then plugged the socket with gauze saturated with the same solution. As the patient could not be induced to remain quiet I gave $\frac{1}{2}$ gr. morphia hypodermically with 1-200 grain Ergotinine cit., and promised to call again in the evening. I was telephoned for again about 2.30 p.m., the message being that the dog was quiet, bleeding had stopped, but there was a great deal of swelling about the face and a "piece of flesh, like a gooseberry" protruding from the facial opening; this I found to be coagulated blood, and the mouth and cheeks absolutely full of the same material—hence the swelling. After clearing away the coagulated blood I again syringed and plugged with adrenalin solution. A quarter of an hour later pure blood was vomited (no vomiting occurred, as is usual, after administration of the morphia) and the bowels were opened, at first blood-stained faeces and then pure blood was passed. After this the dog became rapidly worse, alcoholic stimulants by mouth, and strychnia hypodermically were administered, but death took place within half an hour.

This is the only case of fatal hæmorrhage following tooth extraction I have had out of many hundreds of cases, and am inclined to think that in both this and Mr. Livesey's case the dogs were subjects of hæmophilia, and that fatal hæmorrhage would probably have resulted in any other operation involving laceration of vessels performed on

them. In my case there was no undue laceration of the parts, as the tooth came out quite easily. A dental friend has since told me that he finds turpentine the best agent to employ for plugging sockets when hæmorrhage is profuse after extraction.

CYSTS IN FEET OF DOG.

I enclose photo of a retriever dog's fore feet. The patient, aged 7 years, has been under my treatment one year. As can be seen, one cyst is full; the other has broken out in more than one place and is partially empty. There was another on a hind foot.

Immediately after this photo was taken I opened the three cysts and applied different mixtures to each wound. They all healed about alike; and since, each foot has been affected again, same place, at different times, and another lesion has appeared on the foot that was all right at the time the photo was taken. A cyst will appear in about 18 hours, lameness acute; if left alone it will sometimes break of its own accord in another 18 hours, and lameness gradually disappears. When opened a liquid-like serum escapes tinged with blood, and sometimes there is a little thick pus to finish with.

I have had a good many dogs through my hands as patients during my 26 years practice, but until I moved into a city about one year ago, I had not seen a case of its kind, and now I have at least four cases in dogs of different breeds under treatment for the same trouble.

I am not satisfied.

If any of your readers could tell me; How to cure a cyst and prevent it coming again: How to prevent others coming, and what is the name of the disease? I should be grateful.

A. Z.

ABSTRACTS FROM FOREIGN JOURNALS.

THE ACTION OF "606" UPON GLANDERS IN LABORATORY ANIMALS.

W. Benewolensky has published, from the bacteriological station of the Veterinary Institute at Jurjew (Dorpat), a long and careful study of the action of Ehrlich's preparation "606" upon glanders bacilli and the glanderous processes in small laboratory animals. An abbreviated abstract of this article has been translated from Russian into German by Prof. C. Happich. The following is a brief summary of Benewolensky's methods and results.

Three species of experimental animals were used, viz., rabbits, guinea-pigs, and cats. These were, in the first place, artificially infected with glanders by means of a three days' culture of bacilli in glycerine agar, and were afterwards treated with salvarsan ("606.")

The glanders bacilli were introduced intraperitoneally in the case of guinea-pigs and rabbits, and into the back of the neck in cats. The salvarsan was employed in three different forms, according to the method of its introduction; alkaline solutions were used for intravenous injection, suspensions in sterile liquid paraffin for subcutaneous injection, and neutral suspensions for intramuscular injection. A simple one-gramme or two-gramme injection syringe was used for the subcutaneous and intramuscular injections; a ten-gramme syringe may be used for intravenous injection, but the author prefers a siphon, specially constructed to his design, as being more convenient and safer.

In all 52 animal experiments were performed as follows: 21 on rabbits (of which six were control animals), 16 on cats (of which four were controls), and 15 on guinea-pigs (of which four were controls). These animals, after a short preliminary period of observation, were infected with glanders, and after a definite period of time (which Happich does not specify in his abstract) had elapsed, received one or two injections of salvarsan. Their progress was observed twice daily, and in animals that died, in addition to post-mortem observation, cultural experiments were made with the heart's blood and from the liver and spleen.

In addition to the effect of salvarsan upon glanderous processes *in vivo*, the author also tested its action upon glanders bacilli *in vitro*. For this purpose he used salvarsan in physiological salt solution in twelve different strengths, ranging from 1 in 200 to 1 in 1,000,000; and tested the action of the agent after 1 minute, after 3 minutes, and after 15 minutes.

The result of all the animal experiments showed a very clearly evident influence of salvarsan upon the glanderous processes, and it is especially noteworthy that the duration of the diseased process stood in definite relationship to the quantity of salvarsan injected. This last point was especially clearly manifest in the case of rabbits. Animals

which received a quantity of salvarsan approaching the dose tolerated by the species died *quickly*, while those which received no salvarsan died in due course from the ordinary progression of the disease. Animals which had received a smaller dose of salvarsan, on the other hand, did not die of glanders but lived.

In acute glanderous processes it is possible to sterilise the infected organism by means of salvarsan. The negative results which the author has obtained from cultural experiments with the blood of dead animals confirms this. The author thinks that the destruction of glanders bacilli within the body is probably due to two causes. The destruction of a portion is effected by the chemical action of the salvarsan, and the remainder are destroyed later by antibodies which are formed as a result of the chemical action of the drug.

Minimal doses of salvarsan are therefore requisite for the destruction of the bacteria; and this view is confirmed by the results of the author's experiments *in vitro*. In these it was found that salvarsan in a dilution of 1 in 40,000 killed glands in 1 minute, that a strength of 1 in 100,000 did so in 3 minutes, and that a solution of 1 in 1,000,000 did the same in 15 minutes.

Large doses of salvarsan effect the destruction of an excessively large quantity of bacteria but cause the quick death of the animal from the disintegration products which result from the bactericidal action.

The author finally concludes that salvarsan has a practical importance in addition to a purely scientific one.—(*Zeitschrift für Wissenschaftliche und Praktische Veterinärmedizin*.)

[I wish I could give this research in full detail. If its conclusions are confirmed, and a safe dosage is established for the larger animals, it may prove very important in some countries. Arsenic was one of the drugs which enjoyed a reputation in the treatment of glanders in old days.—TRANSL.]

PRIMITIVE CANCER OF THE LIVER IN A COW.

Meyer records (*Zeitschrift für Fleisch- und Milch Hygiene*) this case, which is a very rare one in veterinary pathology. The subject was an old cow, in perfect health, which had been slaughtered for human food.

The liver was normal in its size, form, and colour, but it was crammed with rounded nodosities ranging from the diameter of a pea to that of a five franc piece. One of these nodosities, however, the largest, had the dimensions of the palm of the hand and was umbilicated at its centre.

All these neoplasms were yellowish-grey in colour and somewhat firm in consistence. Their sectioned surfaces were uniform, and showed no central softening; but scraping them with the knife caused the instrument to become coated with a yellowish-white greasy covering.

The microscopic examination fully confirmed the diagnosis of cancer. Meyer emphasises the absence of metastatic lesions.—*Annales de Méd. Vét.*

W. R. C.

Royal College of Veterinary Surgeons.

FIRST MEETING OF COUNCIL.

A meeting of Council was held at the College, 10 Red Lion Square, London, W.C., on Friday afternoon, 7th July, 1911. Mr. W. Freeman Barrett, President, occupied the chair and the following members were present: Sir John M'Fadyean; Maj.-General Thomson, C.B.; Col. Duck, K.C.B.; Professors Bradley, McCall, Mettam; Messrs. Abson, Banham, Carter, Dunstan, Garnett, Hobday, Lawson, Lloyd, Mcl. McCall, McKinna, Mulvey, Roberts, Rutherford, Slocock, Stockman, Sumner, Wharam; Mr. G. Thatcher, Solicitor; and Mr. Fred Bullock, Secretary.

MINUTES.

On the motion of Mr. Lawson, seconded by Mr. Abson, the minutes of the last meeting were taken as read and confirmed.

ELECTION OF PRESIDENT.

Prof. McCALL: Mr. President and gentlemen, I rise with very great pleasure to propose that Mr. Villar be appointed the President of the College for the ensuing year. I do so principally on two grounds: firstly, that Mr. Villar by seniority of membership is entitled to that honour; but I do it still further, and on even more public basis, that Mr. Villar has during all these years—I think about twelve years—been a most regular attender at our meetings. Not only so, but he has also been Chairman of several Committees, and I am quite sure everyone sitting round the table will acknowledge that he has brought to the discharge of those duties great tact as well as ability. For those reasons I have great pleasure in proposing that he be elected President.

Mr. McKINNA: I have very great pleasure in seconding the motion, that Mr. Villar be elected President of the College for the ensuing year. (Several Members: "He is not here.")

Mr. GARNETT: Mr. Villar assured me yesterday that he would not accept the office.

The PRESIDENT: I should like to say that I am pleased Mr. Villar has been proposed as President, but I myself had some conversation with him yesterday, and he informed me that, owing to the condition of his health, he felt he ought not to accept this honour. I do not know what course I ought to pursue in his absence; he is not here, unfortunately, to speak for himself; but that is the purport of the conversation I had with him yesterday. Are there any other nominations?

Mr. MULVEY: After the statement made by our President, and from what I have gathered from other members of the Council, it seems apparent that Mr. Villar does not feel himself in a position to accept the Presidency of this College. I therefore beg to submit to the Council the name of Prof. Mettam. (Hear, hear). Prof. Mettam is known to all of you. He has been a Member of the Council for many years. He occupies the position of Principal of the Royal Veterinary College in Dublin. He is a man well known for his scientific attainments, and for the position he has taken on this Council. He has been an active worker, and he has attended every meeting of the Committees and of the Council that he could. I should also like to add that we have elected as President members from the various countries, but I do not think Ireland has ever been honoured by having a President elected from their number. I therefore have very great pleasure in proposing Prof. Mettam as the President for the ensuing year. (Hear, hear).

Mr. LAWSON: I have great pleasure in seconding that.

The PRESIDENT: Are there any further nominations? In the absence of Mr. Villar, especially after what he said to me, I do not think I ought to allow his nomination to go any further. May I therefore ask Prof. McCall to withdraw the nomination of Mr. Villar?

Prof. McCALL: I shall be pleased to do so in view of what you say.

Mr. McKINNA: Would it not be a graceful act, knowing that that is so, to pass the resolution that, in the event of Mr. Villar not assenting to accept the Presidency which we wish to offer to him, that Prof. Mettam be elected President?

Mr. MULVEY: You cannot do that.

The PRESIDENT: I am advised I ought not to accept the nomination in Mr. Villar's absence after what he has said, so that perhaps you will kindly withdraw your seconding of the nomination.

Mr. McKINNA: Certainly.

The PRESIDENT: Are there any other nominations? If not I put the motion that Prof. Mettam be elected President of the College for the ensuing year.

The resolution was then put and carried with acclamation.

The RETIRING PRESIDENT (Mr. Barrett), addressing Prof. Mettam, said: I have very great pleasure in announcing that you have been elected President of the Royal College of Veterinary Surgeons, and I have much pleasure in handing you the robe of office and the chain which accompanies it. I am quite sure that you will fulfil the duties of the Presidential Chair with the impartiality which has characterised the Presidents in the past.

Prof. Mettam was then invested with the Robe and Chain of Office, and took the Chair amid hearty cheering.

The PRESIDENT (Prof. Mettam): Gentlemen, I thank you very sincerely indeed for the great honour which you have paid me. I consider it not only a compliment to myself personally, and to the profession in Ireland, but also to the College at the head of which I have the good fortune to be, and to the teachers of the different Colleges generally. I hope that you will have no cause to regret your choice of President; and anything that I can do to uphold the dignity of the Chair and to follow in the footsteps of my predecessors I shall be most happy to do: indeed I shall deem it my duty to do so. I thank you again very much indeed, and I trust I shall receive your sympathy and your assistance while I have the honour of occupying this chair. (Cheers).

It is customary before proceeding to the election of six Vice-presidents to propose a vote of thanks to the retiring President.

Mr. MULVEY: Gentlemen, the duties of the President are very onerous, and I am sure it will be the pleasure of this Council to pass a very cordial vote of thanks to Mr. Barrett for the way in which he has carried out the duties of that office. I beg to propose a vote of thanks to Mr. Barrett.

Mr. McKINNA: I shall be very pleased indeed to second that motion. I am sure we have had a most excellent Preident, and I am confident this Council has in no way been disappointed at the able way in which the College has been represented during the year. I might also say that I congratulate our College that we were so ably represented at the Coronation. The recognition that we received at the hands of the Authorities I have personally felt as a dignity and an honour conferred upon the profession. I very heartily second the motion.

Sir JOHN M'FADYEAN: Although I feel quite sure that no further words are necessary in order to commend this Council the motion which has just been formally

proposed and seconded, I ask leave to be allowed to say a few words in support of it. (Hear, hear). Our newly elected President has just said it is customary to offer the thanks of the Council to the retiring President, but I want to emphasise the fact that at least in this case it is no empty formality. (Hear, hear). I wish to associate myself most fully with what has just been so well said by Mr. Mulvey and Mr. McKinna. I think it is very largely due to the personal influence of our late President that the business of the Council has been carried through with such smoothness and celerity. I am quite sure you will all agree with me when I say that everything he has had to do in connection with his office has been done in a manner reflecting further credit on the dignity of the chair. (Hear, hear). Apart from what might be called the ordinary routine business which this Council has to transact, our principal anxiety during the past year has been in connection with the Bill which we have promoted in Parliament. Unfortunately, the Bill so far has not made very great progress, but that is, I venture to say, due to circumstances over which we have very little control. As Chairman of the Committee which has had special charge of the Bill, I have had better opportunities than most members of the Council of observing the whole-hearted manner in which our late President has sought to secure the passing of this Bill into law, and for what he has done in that connection this Council and the profession at large owe him a debt of gratitude. (Hear, hear); and my principal purpose in rising was to give public expression to our sense of that duty. (Cheers).

The PRESIDENT: I shall not put this resolution; we will carry it by acclamation.

The resolution was then put, and carried by acclamation.

Mr. BARRETT, who was received with cheers on rising to reply, said: Mr. Mulvey, Mr. McKinna, Sir John M'Fadyean and gentlemen, I desire to thank you very much for the cordial vote of thanks which you have carried by acclamation. I confess to you at once that that has pleased me very much, because there is no gainsaying the fact that twelve months ago, when you conferred the very distinguished honour upon me of making me your President, I entered upon the duties of the office with some misgiving. I did that because I was called to the Chair perhaps in exceptional circumstances. There were some sitting round this table who doubted my patriotism to the profession, forgetting that although I belong to another profession this, after all, is the profession which I love and which I always desire to be attached to. (Hear, hear.) I am peculiarly gratified at the remarks which have fallen from Sir John M'Fadyean, because his announcement to you that, during my year of Presidential office, I have carried out loyally and patriotically the promise which I made to you is an indication to me that one and all of you feel that I have done my very best for the profession and for the Council which I have had the honour to represent. To me it has been a source of anxiety that the Bill which is now before Parliament has made such slow progress, but you have it from Sir John M'Fadyean—and therefore I need not repeat it—that we all of us have done what we can in order to further the objects of the Bill. The House of Commons has been very much congested with business, and we have not had much voice in the matter. It is a source of intense gratification to me, if I may say so, to feel that I have merited your approbation for what I have done. I have not done very much. By my influence, perhaps, I procured the assistance—if I may say so the valued assistance—of Sir Frederick Low, and I would like to testify to you openly that this gentleman in my view is taking a very great interest in our measure and has done everything he possibly could to further the interests of the Bill. (Hear, hear.) Gentlemen, I feel I ought not to sit down without referring to two

gentlemen who are in this room now. I refer first of all to Mr. Thatcher. I confess to you at once during the last few months I have not been in very good health; I have been over-taxed with work, professional work and municipal work, and the responsibilities of the office of President; and I have some misgivings—they certainly exist in my own mind—that perhaps I have not been quite as active as I ought to have been. That I have been patriotic and honourable to the profession there cannot be the least question, but I have put upon Mr. Thatcher's shoulders perhaps greater responsibilities than he could have been asked to perform, and I wish now to testify to the very great interest he has taken in this measure. He has seen Sir Frederick Low several times with regard to the Bill, and he has interviewed Members of Parliament. He has converted those who were at one time opposed to the measure, and he has been largely instrumental in propitiating, in diminishing—if I may use the term—the opposition of the Highland and Agricultural Society. Gentlemen, I say this to you: You never can sufficiently repay Mr. Thatcher for what he has done, and I desire, at the close of my Presidential year, to testify to him my appreciation of his kindness on my behalf.

Then, sir, during the past year I have really had very little trouble in connection with the work of the College owing to the assiduous and efficient attention which has been given to the business of the College by Mr. Bullock (Hear, hear.) He has saved me in every possible way. I would like to say that in him we have a most excellent Secretary, and I, personally, in the presence of you all, desire to thank him for what he has done for me.

In conclusion, I should like to say that I very much appreciate the honour which you conferred upon me last year. I suppose it is a laudable ambition that a countryman, a man born in a little village, should attain to the position of the Presidential Chair, and I feel that honour very much. I am even more gratified that, at the close of my term of office, I have met with your approbation. (Cheers.)

ELECTION OF SIX VICE-PRESIDENTS.

On the motion of Mr. Abson, seconded by Mr. Sumner, the following six members were elected Vice-Presidents: Messrs. Barrett, Carter, Dunstan, Hobday, Roberts, and Slocock.

ELECTION OF TREASURER.

Mr. LAWSON: I beg to move the re-election of Mr. Mulvey as Treasurer of the College. He has been the Treasurer ever since our friend Mr. Wragg died, and I believe he has given satisfaction to the whole of the Council and the profession at large. He has been on a bed of sickness for a month or two, and we are very glad to see him back again with us in good health. His greatest difficulty always is to find money. He is always working on the economical side, and pointing out to us the various ways in which we are spending money. If he could only increase it instead of decreasing it I think he would be happy. (Laughter). Gentlemen, I have the greatest possible pleasure in moving the re-election of Mr. Mulvey.

Mr. ROBERTS: I should like to have the opportunity of seconding the proposition. The Members of the Finance Committee know well that Mr. Mulvey husbands the finances of the College, and it is a great personal pleasure to me to be able to second the motion.

The resolution was then put and carried with acclamation.

Mr. MULVEY, who was received with cheers on rising to reply, said: Gentlemen, I can only thank you for the honour you have once more conferred upon me. As Mr. Lawson has pointed out, the difficulty always is to obtain funds to carry on the work of this College. I only hope that this newly-elected Council will devise some means for increasing the funds that we can use.

ELECTION OF SECRETARY AND REGISTRAR.

Mr. BARRETT: May I have the pleasure of rising to move the re-election of Mr. Bullock as Secretary and Registrar. After what I said a moment ago, I do not think I need say very much. He is a most excellent officer, and I am quite sure he will be unanimously re-elected.

Mr. MULVEY: As one who has worked with Mr. Bullock ever since his appointment I desire to second the motion, and to add my meed of praise for the way in which he carries out his work.

The resolution was put and carried with acclamation.

The SECRETARY (Mr. F. Bullock): Gentlemen, I thank you very much for your re-election.

This concluded the business of the meeting.

QUARTERLY MEETING.

A quarterly meeting of Council was held immediately following the above meeting.

The PRESIDENT occupied the chair, and the same members were present as at the previous meeting.

MINUTES.

On the motion of Mr. Barrett, seconded by Major-General Thomson, the minutes of the last meeting were taken as read and confirmed.

APOLOGIES FOR ABSENCE.

The SECRETARY announced that communications, regretting their inability to attend, had been received from Messrs. Dewar, Mason, Trigger, Villar, and Williams.

OBITUARY.

The SECRETARY read the obituary list.

ADMISSION TO MEMBERSHIP.

The SECRETARY read the following list of new members admitted since the previous quarterly meeting:—*Edinburgh College*.—Messrs. L. A. Auchterlonie, W. D. Connochie, W. Halstead, D. A. Hosford, J. B. Idle, W. J. E. Mackenzie, C. Masson, R. E. Murison, P. B. Riley, H. L. Torrance, R. Wooff.

Glasgow College.—Messrs. J. Cunningham, H. McC. Johnston, P. Meikle.

London College.—Mr. H. D. Sparrow.

Liverpool College.—Mr. H. L. Sowerby.

CORRESPONDENCE.

The SECRETARY read a letter from Mr. R. H. Lambert, in which he conveyed the sincere thanks of his mother and himself to the Council for their very kind expression of sympathy and condolence in their recent bereavement.

The SECRETARY read a letter dated April 13th, 1911, from Mr. G. P. Male, Secretary of the Royal Counties Veterinary Medical Association, which stated that at the last meeting of that Association the following resolution was unanimously adopted, and he was requested to place the same before the Council of the Royal College:—"That the members of the Royal Counties V.M.A. unanimously request the Council of the Royal College of Veterinary Surgeons to do everything in their power with a view to obtaining a rebate off the Petrol and Motor Taxes for members of the veterinary profession to the same extent as has already been granted to the sister medical profession."

The SECRETARY announced that he had received a programme of the Seventh International Tuberculosis Congress to be held in Rome on September 7th next.

RIGHT OF WAY.

The SECRETARY: I have to report that, in accordance with annual custom, I passed through the doorway into

Yorkshire Grey Yard in order to establish the right of way.

PRESENTATIONS TO THE LIBRARY.

The SECRETARY announced that the following presentations had been made to the Library since the last meeting of Council:—Calendar of the College of Preceptors, 1911-12; Twenty-sixth Annual Report of the Bureau of Animal Industry, 1909; Union of South Africa, Department of Agriculture, Report of the Government Veterinary Bacteriologist for the year 1909-10; Reports of the Council and Auditors of the Zoological Society of London for the year 1910; *The Rhodesian Agricultural Journal*, April, 1911; *Journal of the Board of Agriculture*, April, May and June, 1911, together with General Indexes for Volumes I-X. and XI-XVII.; Leaflets of the Board of Agriculture and Fisheries; *The Journal of Meat and Milk Hygiene*, April, May, and June, 1911; Bulletins of the Sleeping Sickness Bureau, April and May, 1911; Bulletin of the Yellow Fever Bureau, May, 1911; *Revue de Pathologie Comparée*, March, April, and May, 1911; *The Veterinary Journal*, *The Veterinary News*, and *The Veterinary Record* for the quarter.

On the motion of Mr. Mulvey, seconded by Major-General Thompson, a hearty vote of thanks was accorded to the respective donors.

FINANCE COMMITTEE.

The SECRETARY read the following report of a meeting of the Finance Committee held on Friday, June 7th, 1911:—

Financial Statement.—The TREASURER submitted the quarterly financial statement, showing a deficit of £364 15s. 5d., and further liabilities amounting to £203 2s. 11d.

It was resolved that the Treasurer be ordered to pay the liabilities due, together with cheques for monthly salaries, examiners' fees and expenses, and examination expenses, London, Liverpool, and Dublin, for gas and electric light, and an additional account which had been received from the Solicitors acting on behalf of the trustees of Mr. J. F. Simpson, the settlement of which was left in the hands of the Treasurer and Solicitor.

Overdraft. The Treasurer reported that he had been unable to agree to the terms proposed for the guarantee of £1,000, and that he would therefore be under the necessity of selling out Consols to that amount, in accordance with the resolution of Council in January last.

Auditor's Report. The Treasurer stated that the auditors had reported that the books of the College were kept in good order, and that the accounts and vouchers were correct.

Donations. The Secretary reported that further donations amounting to £13 13s. had been received, making a total amount received of £90 6s.

And it was resolved that the thanks of the Council be accorded to the respective donors.

Trustees. It was reported that the proceedings for the transfer of the Stock held by the College into the names of Sir John M'Fadyean, and Messrs. R. C. Trigger and A. Lawson, had now been completed.

Memorial Funds. The Secretary reported that the Walley Memorial and Jubilee Memorial Prize Funds had been transferred to the jurisdiction of the Charity Commissioners.

He further stated that the income from the respective funds would now be received by the College without deduction of Income Tax.

Mr. LAWSON: I move that the report be received and adopted.

Mr. SUMNER: I second that.

Mr. MULVEY: Before you put that motion to the meeting, there are one or two remarks connected with

the finances of the College that I think I ought to make. The first is, that the total of the liabilities is not quite fully stated in the report of the Committee. Since this account was drawn up I have received a further account amounting to £7 6s. 2d. for the solicitor's charges *re* trusteeship; bank charges amounting to £6 12s.; a Power of Attorney amounting to 11 6, and brokerage fees of £5 1s. 3d., making a total of liabilities of £587 9s. 3d. I mention that so that you may be in the position to understand that, although I propose now to sell out £1000 worth of Consols, which will realise some £780, we shall not be in a very flattering condition even then. We shall have to repay the Bank an overdraft of £570, which will only leave us some £200 to work with. So that I want this Council fully to understand that, at its next quarterly meeting, the probabilities are I shall have to ask for power to sell another £1000 worth of Consols, so that unless we have further funds coming in, our £8000 will not last very long. Every year our financial position is getting worse. The auditor in his report drew my attention to the fact that no provision had been made for the deterioration or dilapidation which is necessarily occurring to this building, and we must remember that in a very short time we shall have to find a certain amount for substantial repairs. That has to be faced. I think the profession must now admit that we are not in quite as flourishing a condition as either they or the members of this Council would desire that we should be. Every effort has been made to curtail expenses, and I see very little chance of making them any less. There is only one little item that I should like to refer to—and I am very sorry to have to refer to it. Our examination expenses do not get any less, and if we could only persuade Prof. McCall and those who act with him to agree to having one centre of examination in Scotland, as we have tried to induce him to agree to on several occasions, it would be certainly a means of saving this College a certain amount every year. With those remarks, gentlemen, I must leave the matter in your hands.

The resolution for the adoption of the Report was then put and carried.

REGISTRATION COMMITTEE.

The SECRETARY read the Report of a meeting of the Registration Committee held on July 6th, which stated that under the head of Correspondence four complaints were dealt with, and the Secretary was instructed with regard to the reply to be sent in each case.

Cases. Thirteen cases were dealt with by the Committee, and the Solicitor or Secretary were instructed with regard to the course to be pursued in each.

College Arms. The Solicitor asked for instructions for the reply to a letter received asking for information, which he was instructed not to supply.

Witnesses' Fees. A letter was received from Mr. Abraham Green raising a question with regard to witnesses' fees payable in the County Court.

It was resolved that the Secretary be instructed to reply that the general rule is that witnesses are entitled to fees and allowances as are set out in the scale applicable to the tribunal before which they give evidence, and this applies to veterinary surgeons the same as to other people.

With regard to expert evidence, or matters of opinion and not of actual fact, the witness is not bound to give evidence, except he is reasonably remunerated, and he can refuse to do so; his proper course is to mention his objection to a judge. An expert witness should always however make his bargain beforehand, both for qualifying and giving evidence.

Maj.-Gen. THOMPSON: I propose that the Report be adopted.

Mr. GARNETT: Before the Report is adopted, there is one matter I think it would be advisable that this

Council should have placed before them. I move, therefore, that the Council resolve itself into Committee to consider a case of professional misconduct which should be dealt with at this meeting.

Mr. ABSON: I beg to second that.

The resolution was put and carried.

The Council then resolved itself into Committee, and on the resumption of the Council meeting, General Thomson moved that the Report of the Registration Committee, with the addition of the result arrived at during the recent deliberation of the Council in Committee, be received and adopted.

Mr. BARRETT seconded the motion, which was carried.

EXAMINATION COMMITTEE.

The SECRETARY read the following Report of a meeting of the Examination Committee held on Thursday, July 6th:—

Reports on the Scotch Examinations. The Reports of the Delegates, Chairmen of the Board of Examiners, and the Local Secretaries were read and considered, and it was resolved—

That a letter of thanks be forwarded to the Glasgow and West of Scotland Technical College for the use of the room for the Written Examination.

Educational Certificates. (a) Educational Certificates Nos. 1183 to 1185 were received and accepted.

(b) The Secretary reported that a further certificate of a candidate desiring to sit at the forthcoming examinations was yet to be received.

And it was resolved that the Chairman of the Committee and the Secretary be empowered to accept it if it complies with the bye-laws.

Correspondence. A letter was received from Mr. W. Robb stating that on account of the illness of his father, he would be unable to act as Examiner at the forthcoming examinations. The Secretary reported that, after consultation with the President, arrangements had been made for Mr. W. Cargill Patrick to act in his stead.

And it was resolved (a) that the action of the President be approved.

(b) That in any case where an Examiner is unable to act for any part of the Examination, he be required to give due notice to the Secretary, and that a substitute be appointed to act in his stead at each centre at which the Examination is to be held.

Edinburgh University Ordinance. It was resolved that copies of the Edinburgh University Ordinance be obtained and submitted to the Examination Committee at the next meeting.

Examination Bye-laws. The Examination Bye-laws were further considered.

And it was resolved that the matter be deferred for further consideration at the next meeting.

Examination Questions. It was resolved—

(a) That the Secretary be instructed to print the names of the Examiners at the head of each examination paper, and to supply copies of past questions to students and others at a charge to be decided upon.

(b) That the questions set in each year be published as an appendix to the Register.

On the motion of Mr. LAWSON, seconded by Major-General THOMPSON, the Report was received and adopted.

ANNUAL FEE COMMITTEE.

Sir JOHN McFADYEAN read the following Report of a meeting of the Annual Fee Committee, held on Thursday, July 6th.

Draft Amendment Bill. (a) The Secretary read a letter received from the Highland and Agricultural Society stating that the Society had decided to withdraw their opposition to the Bill under certain conditions.

It was resolved that, in the opinion of this Committee, as the matter is one which requires very serious consideration, it be referred to the President, Chairman of Committee, and the Solicitor, with instructions to continue negotiations with the Highland and Agricultural Society, and to endeavour to obtain the consent of the Society to reconsider, and if possible to withdraw, or modify the stipulations contained in their resolutions.

(b) The Solicitor reported that the second reading of the Amendment Bill had not yet been reached, and that no information is obtainable as to when it would next be considered.

Mr. THATCHER: I can amend that report by saying the Bill will come on next Monday, or it is down for reading next Monday.

On the motion of Sir John M'Fadyean, seconded by Major-General Thomson, the Report was received and adopted.

PUBLICATION COMMITTEE.

The SECRETARY read the Report of a meeting of the Publication Committee, held on Monday, May 8th, which stated that the Annual Report was considered, and after emendation was approved.

The Secretary also submitted the draft of the voting paper to be issued on May 24th, which was duly approved.

On the motion of Mr. Mulvey, seconded by Major-General Thomson, the report was received and adopted.

MELBOURNE UNIVERSITY DEGREE COMMITTEE.

The SECRETARY read the following Report of a meeting of the Melbourne University Degree Committee, held on Thursday, July 6th.

Melbourne Veterinary Degree. A letter (4/5/11) was received from the Colonial Secretary, together with a communication (11/3/11) from the Premier of Victoria, containing information with regard to the course of instruction and subjects of examination for the Degree in Veterinary Science granted by the Melbourne University.

It was resolved that the Secretary be instructed to reply in the following terms:—

Sir,—The Council regret that the information supplied in the despatch from the Premier of Victoria which accompanied the Agent General's letter does not lend them to think that the Veterinary Degree of the University of Melbourne is one which they ought to recognise in accordance with Section 13, sub-section (3) of the Veterinary Surgeons Act, 1881.

As stated in my letter of the 21st July, 1909, the Council have always interpreted that portion of the Act to mean that they must "recognise" any veterinary diploma granted in a British possession if they are satisfied that the diploma in question is as a guaranty of professional competence equal to the Membership Diploma of the Royal College of Veterinary Surgeons.

The value of the diploma granted by this College as a guaranty of professional knowledge and competence depends upon two things which are mutually complementary, namely:—

1. Every candidate for the diploma must, for a specified period, attend prescribed courses of study at one of the Veterinary Schools in Great Britain or Ireland which are affiliated to the Royal College of Veterinary Surgeons.

2. Every candidate must pass professional examinations which are conducted by a Board appointed by and under the supervision of this Council.

In the opinion of the Council it is especially in respect of the second of these that the Veterinary Degree of the University of Melbourne fails to afford a guaranty of professional competence equal to that of the diploma of the Royal College of Veterinary Surgeons. The Examining Board appointed by this College comprises twenty-

two members, all of whom are appointed because of their recognised eminence in the particular subject on which they have to examine, and, in accordance with an express provision of the Charter from which the College derives its powers to examine students and grant diplomas (original Charter of 1844), the professors in the several affiliated Colleges are debarred from taking any part in the examination of their own students. It ought to be added that during the last twenty years the Board has always comprised two examiners (both professional experts) for each subject of the curriculum. From its constitution, therefore, the Board affords a guaranty that the candidates for the diploma will in each subject be examined by two experts who are free from the interest or bias which is likely to have an influence when a teacher is asked to judge of the competence of his own students.

The constitution of the Board which examines candidates for the veterinary degree of the Melbourne University is, however, different from this, and in the opinion of my Council open to serious objection. In the Premier's letter of the 11th March last it is stated that the Examiners "are the whole body of teachers sitting as a Board," and, as there is only one teacher for each subject, and the teacher in one subject cannot be regarded as competent to examine in any other (*e.g.* the Professor of Chemistry to examine in Veterinary Pathology), it follows that the sole judge of a candidate's competence in any subject is the single Professor who has instructed him in that subject.

In other words the system of examination is the very one which is expressly forbidden in the Charter of the Royal College of Veterinary Surgeons, and which it would not be lawful for the Council to sanction in the case of veterinary students who receive their education in Great Britain or Ireland.—I am, sir, your obedient servant,

(Signed) F. BULLOCK, *Secretary.*

On the motion of Prof. McCall, seconded by Sir John M'Fadyean, the report was adopted.

APPOINTMENT OF COMMITTEES FOR THE YEAR.

Mr. LLOYD: Before we appoint the members of the Committees I would like to call attention to the peculiar, if not anomalous representation of members of the Council on the different Committees. In an idle moment I took the trouble to go through the list of Committees and note the various Committees upon which certain members had seats. In the list for 1909-10, excluding the President and the Registration Committee, which is composed of the whole of the Council, I found there were nine Committees with a total of 117 seats. Seven members between them—taking five as the minimum held by one member—held 47 seats, which equals 40.1 per cent. of the total. The other 24 members held 70 seats between them, equal to 59.9 per cent. Now taking 1910-11, and again excluding the President and the Registration Committee, there were eight Committees with a total of 109 seats between them. I find that seven members—the same seven as in the previous year—held 43 seats, equal to 39.4 per cent. of the total; and the other 24 members held 66 seats, equal to 60.6 per cent. The matter is one which I think requires a little consideration on behalf of the members of this Council. I, personally, at any rate, look upon it as a waste of time to come here, we will say, to the Registration Committee at 2 o'clock on a Thursday and after the conclusion of the meeting of that Committee waste the whole of the afternoon, whereas I might be taking an active part in the work of the Council. I do not know whether any other gentleman present feels it in that way, but certainly that is my feeling. You may possibly ask me, What is the remedy? Three things occurred to my mind. The first was that

all Committees shall consist of the whole of the Council. I should probably meet with the objection, if I suggested that, that any Committee so formed would be unwieldy. That objection of course applies to the Registration Committee, as at present formed, and I do not think it would carry any more weight with regard to any other Committee than it does to that one. The second remedy would be to limit the number of Committees that any one member should have a seat on. I do not know whether that is at all practicable. If it is I think it would perhaps be an easy out of the difficulty. A third way, which I think probably would be the best, would be that gentlemen who are over-represented, as I have stated, on various Committees, should use their good sense and withdraw, so that they would not hold the membership of more than a certain number of Committees. I am not going to make any proposition; I simply throw out the suggestion for what it is worth, and I ask you seriously to consider it.

Sir JOHN M'FADYEAN: I should like to suggest, Mr. President, that a misunderstanding or misconception underlies the remarks that have just been made by Mr. Lloyd. I may have misunderstood him, but it seemed to me that what he said would justify one in inferring that, in his belief, the Council appointed members to serve on Committees in order to do these members an honour. That I think is quite a mistaken view of the matter. (Hear, hear.) The sole consideration which ought to guide the Council is what constitution of a Committee will best secure that the business of that Committee is transacted in the best manner—(hear, hear)—and while I should cordially agree with Mr. Lloyd's suggestion that it is well worthy of consideration whether some of the Committees are not at present too large, I do not think the Council should tie its hands in any way with regard to the composition of the Committees. I should support what Mr. Lloyd has said as regards the desirability of limiting the size of some of the Committees, but not that we should pass any resolution that a member should not serve on more than a certain number of Committees.

Mr. GARNETT: I think it would facilitate business if I propose that, with the exception of the Registration Committee, no Committee shall exceed in number 16 members. I moved in that respect two or three years ago, and the motion was carried, but the rule has been broken through again, and we now have very large Committees. To my mind it is improper that any Committee should consist of a majority of the Council, because it means that if those Committeemen have a majority greater than the members of the Council, they practically resolve themselves into the Council, and the minority have no voice at all. I propose that no Committee, with the exception of the Registration Committee, exceed 16 members.

Mr. LLOYD: I am quite prepared to second Mr. Garnett's proposal if he will accept also a number as a minimum for the members of any Committee.

Mr. GARNETT: You must leave that in the hands of the Council. The Council might want to appoint a small Committee to deal with a special object.

Mr. LLOYD: I am speaking of standing Committees; I am not speaking of any special Committee. I am not taking special Committees into consideration in any shape whatever. If I am in order I propose that the minimum number for any standing Committee be 12.

Mr. WHARAM: I beg to second Mr. Garnett's proposition.

Mr. MCKINNA: When we have had a congestion of business we have got out of the difficulty by proposing the election of Sub-committees, and that has acted very well. The Report of the Sub-committee has been brought forward to the next meeting of the full Committee, which has dealt with the matter. As to the Registration Committee I, for one, would not be agree-

able to any suggestion that the whole Council should not share the responsibility of the work that it does.

Mr. GARNETT: In reply to Mr. McKinna, I might say that we have found the Parliamentary Committee very unwieldy, and it is very inconvenient to delegate powers to a Sub-committee. We had to do our business in a rather irregular manner, as Mr. McKinna knows, on one or two occasions during the past year, owing to the necessity of delegating power to Sub-committees which had not time to report to the Main Committee before reporting to the Council.

Sir JOHN M'FADYEAN: On a point of order I would like to enquire whether we have any power to lay down such a regulation except with regard to our action on this occasion. I take it we cannot tie the hands of the Council in this matter unless it were a new bye-law which were being moved of which formal notice had to be given. We can only pledge ourselves to act in conformity with this regulation on this occasion.

The PRESIDENT: Yes, that is so. It is proposed by Mr. Garnett and seconded by Mr. Wharam, that with the exception of the Registration Committee the number of members on a Committee shall not exceed 16.

The SOLICITOR: I have to call the attention of the Council to the bye-law on the subject. Bye-law 18, which deals with this matter, says, "All standing Committees shall consist of not less than seven members, of whom three shall form a quorum."

Mr. GARNETT's motion was then put and carried.

The following Committees were then appointed:—

REGISTRATION COMMITTEE.

The whole Council.

EXAMINATION COMMITTEE.

Messrs. O. C. Bradley, J. H. Carter, F. Duck, J. Dunstan, F. T. G. Hobday, J. S. Lloyd, J. McCall, Sir J. M'Fadyean, J. McKinna, W. J. Mulvey, R. Roberts, S. Stockman, H. Sumner, H. Thomson, S. Villar, W. O. Williams.

FINANCE COMMITTEE.

Messrs. J. Abson, W. F. Barrett, O. C. Bradley, F. W. Garnett, A. Lawson, J. S. Lloyd, J. McKinna, A. W. Mason, W. J. Mulvey, R. Roberts, R. Rutherford, W. Shipley, H. Sumner, R. C. Trigger, S. Wharam, W. O. Williams.

PARLIAMENTARY AND GENERAL PURPOSES COMMITTEE.

Messrs. J. Abson, W. F. Barrett, O. C. Bradley, J. H. Carter, F. W. Garnett, A. Lawson, Sir John M'Fadyean, J. McKinna, A. W. Mason, W. S. Mulvey, J. S. Lloyd, R. Roberts, S. Stockman, H. Sumner, H. Thomson, W. O. Williams.

ANNUAL FEE COMMITTEE.

Messrs. W. F. Barrett, F. W. Garnett, J. McCall, Sir J. M'Fadyean, W. S. Mulvey, H. Sumner, H. Thomson, R. C. Trigger.

LIBRARY AND MUSEUM COMMITTEE.

Messrs. J. Abson, G. A. Banham, O. C. Bradley, J. H. Carter, J. Dunstan, F. T. G. Hobday, Sir J. M'Fadyean, W. J. Mulvey, E. S. Shave, S. H. Slocock, S. Wharam, W. O. Williams.

PUBLICATION COMMITTEE.

Messrs. J. Abson, J. McCall, J. McI. McCall, Sir J. M'Fadyean, W. J. Mulvey, J. S. Lloyd, R. Roberts, S. Stockman, S. Villar, S. Wharam, W. O. Williams.

STEEL MEMORIAL COMMITTEE.

Messrs. J. Abson, O. C. Bradley, J. McCall, Sir J. M'Fadyean, W. J. Mulvey, R. C. Trigger, R. Roberts.

HONORARY ASSOCIATES COMMITTEE.

Messrs. G. A. Banham, O. C. Bradley, J. R. U. Dewar, A. Lawson, J. McCall, Sir John M'Fadyean, S. Stockman.

ELECTION OF AUDITORS.

Mr. MULVEY: I beg to propose the re-election of Messrs. Woodhouse and Wilkinson as auditors. They have heretofore performed their duties in a very satisfactory manner, and I therefore propose that they be re-elected.

Mr. ROBERTS seconded the motion, which was carried unanimously.

DATES OF COUNCIL AND COMMITTEE MEETINGS AND EXAMINATIONS DURING THE ENSUING YEAR.

The following dates were fixed for the Committee and Council meetings: 1911, October 12th and 13th; 1912, January 11th and 12th; April 11th and 12th; July 4th and 5th.

Prof. M'FADYEAN: With regard to the dates of the examinations, I would suggest that we should select the nearest corresponding dates to last year. I would therefore move that the Written Examinations in December be held on the 8th, the Oral Examinations to begin on the 12th. I would like to point out that if we select those dates it will be necessary for the Colleges to open on the first available day in October.

Mr. BARRETT seconded the motion, which was carried.

Prof. MCCALL: I will move that the Written Examination in May be held on the 24th, the Oral Examinations to begin on the 28th.

Prof. BRADLEY seconded the motion, which was carried.

Sir JOHN M'FADYEAN: I move that the Written Examination in July be held on the 12th, the Oral Examinations to begin on the 16th.

Prof. MCCALL seconded the motion, which was carried.

DATE OF WALLEY MEMORIAL PRIZE EXAMINATION.

On the motion of Mr. Barrett, it was agreed that the Walley Memorial Prize Examination should be held on the Saturday before the opening day of the Colleges, namely, the 30th Sept., 1911.

FELLOWSHIP EXAMINATION.

It was resolved that the Fellowship Examinations should be held on the 2nd December, 1911, and the 18th May, 1912.

OTHER BUSINESS.

The SOLICITOR: This is not perhaps in order, as it is an application for the restoration of the name to the Register. The parties only came here late yesterday afternoon after the Registration Committee had adjourned. It is a matter of some importance to this gentleman to be able to practise at once, and I was asked whether, as a matter of indulgence, you would allow the application to be considered now. The application is made by Mr. John Winfield Reynolds, and the reason he has not applied before, and the way his name got taken off the Register, was because—"I did not receive the Notices owing to my being abroad, and the letters appear to have been neglected by the Post Office officials in Moravia." The declaration is in order.

Prof. HOBDAY: I know this gentlemen personally; he is an old College friend of mine.

Mr. MULVEY: If Mr. Thatcher assures us that the application is in order, I move that the name be restored.

Mr. MCKINNA: I second that.

Maj.-General THOMSON: Is it not necessary first of all for us to resolve ourselves into the Registration Committee to consider the application?

Mr. MULVEY: Not necessarily. The Council can do it.

Maj.-General THOMSON: I am quite satisfied. The resolution was put and carried.

VOTE OF THANKS TO THE PRESIDENT.

On the motion of Mr. McKinna, seconded by Prof. McCall, a hearty vote of thanks was accorded to the President for his conduct in the chair, which the President briefly acknowledged, and the meeting terminated.

INTERNATIONAL VETERINARY CONGRESS 1914.

A special meeting called by Sir John M'Fadyean and Mr. S. Stockman was held at 10, Red Lion Square, on Thursday, the 6th instant, when the following gentlemen attended:—Messrs. J. Abson, N. Almond, G. A. Banham, W. F. Barrett, F. Bullock, J. H. Carter, W. R. Clarke, A. Crabb, Sir F. Duck, J. Dunstan, F. W. Garnett, F. L. Gooch, W. L. Harrison, F. T. G. Hobday, W. Hunting, A. Lawson, J. S. Lloyd, J. McCall, Sir J. M'Fadyean, A. E. Mettam, R. Roberts, R. Rutherford, S. Stockman, H. Sumner, S. Villar, S. Wharam, J. Willett, A. Wilson, H. A. Woodruff and G. H. Wooldridge.

In opening the proceedings Sir John M'Fadyean said:

As perhaps some of you know, at the last meeting of the International Veterinary Congress, which was held at The Hague in 1909, Mr. Stockman and myself were appointed as an Organising Committee for the next Congress to be held in London in 1914, with power to add to our number. Possibly some may think that we were remiss in having allowed such an interval to elapse without doing anything to discharge the duty laid upon us, but I do not think that we are really guilty in that respect. It has to be remembered that the next Congress will not be held until 1914, and there appears to be ample time now to arrange all the business. My original idea was that Mr. Stockman and myself should constitute the Committee by co-opting all the members of Council on the Royal College of Veterinary Surgeons to begin with, and that the thing might then be allowed to proceed, the Committee as thus constituted adding any members that they thought wise. We have, however, thought it well to invite a few other gentlemen to join the Committee at the start, viz., Profs. Macqueen, Woodruff, and Wooldridge, Messrs. J. G. Bell, F. G. Samson, M. Hedley, T. S. Price, W. Woods, F. L. Gooch, J. Willett, W. L. Harrison, W. Hunting, N. Almond, W. R. Clarke, J. J. Kelly, A. Crabb, A. I. McCallum, C. Stephenson, and F. Bullock. Invitations to attend this meeting have accordingly been sent to these gentlemen, as well as to the members of the Council of the R.C.V.S. I suggest that the first business of the committee should be to appoint a Chairman, a Secretary, and a Treasurer.

Mr. BARRETT then moved, and Principal McCall seconded, that Sir John M'Fadyean be elected Chairman, and on being put to the meeting this was carried. Sir John M'Fadyean having taken the Chair, Mr. Barrett moved, and Mr. Banham seconded, that Mr. Stockman be appointed Secretary. This also was carried, and on the motion of Mr. Banham, seconded by Mr. Lawson, Mr. Garnett was elected Treasurer.

The CHAIRMAN: I have had excuses for absence from Mr. Mason, Mr. Trigger, Prof. Macqueen, and Prof. Dewar. I would like to suggest as the next business that we should consider the propriety of enlarging the Organising Committee by co-opting still further members. I throw out the suggestion that the Chairmen and Secretaries of the various Veterinary Societies should be appointed *ex-officio* members of the Organising Committee.

Mr. CARTER: I beg to second that.

The resolution that the Chairmen and Secretaries for the time being of the various Veterinary Societies be

elected *ex-officio* members of the Organising Committee, was then put to the meeting and carried.

The CHAIRMAN: I also propose that the present Director-General of the A.V.S., Major-General Pringle, be asked to join the Organising Committee.

Mr. ABSON seconded, and the motion was unanimously carried.

The CHAIRMAN: May I now say, gentlemen, that I think there is plenty of work for the Committee to set about immediately. I have already stated that it did not appear to Mr. Stockman and myself that there was any good in calling the Committee much earlier. But it is quite certain there is plenty of work now. The all-important work is to get in money. (Hear, hear.) I do not think there is really any other work for the Organising Committee to do during the next twelve months except to collect money. We cannot begin to make arrangements for holding meetings or reading of papers; we cannot proceed to decide what subjects are to be discussed at the Congress, or decide who is to be invited to read a paper on any particular subject, for about two years yet. It is not customary to decide such matters until a year before the Congress actually meet. But meanwhile we have got this all important business of raising money to tackle, and the question is, how much money shall we require to raise. Well, the amount of money that has been expended in connection with preceding Congresses has varied a good deal on different occasions, but I think the tendency has been for the holding of the Congress to become more expensive, and I have made a rough calculation that if the Congress is to be anything like as successful as recent Congresses have been, we shall require £5,000. It has to be remembered that there will probably be about 1,500 subscribing members who pay £1 each, so that is so much that will not have to be raised by voluntary subscriptions. But I am perfectly satisfied that the minimum sum which will enable us to carry the Congress through in addition to that got from regular subscriptions is from £3,000 to £3,500. And the next question is, where can we get that money? One may begin by indicating places where it is not to be had. One of these is from the Government. I have had it suggested that we should ask the Government for assistance to carry through the Congress. Gentlemen, I think that would be a waste of time and energy. We could not expect the Government of this country to create a new precedent in our favour. There have been many Congresses held in London within recent years, and I think I am right in saying that none of these have had any grant from Government for the purpose of carrying through their business. I cannot think of any body outside to whom we have any good right to appeal for assistance. This is a Veterinary Congress. It is an occasion on which we are called upon to return hospitality that has been dispensed to representatives of this country at preceding Congresses, and if there ever was an occasion this is one where members must put their hands into their pockets and subscribe as far as their means allow. It is a matter to which I have given a great deal of anxious thought ever since the day when Mr. Stockman and myself were appointed as a nucleus of this Committee, and I had the notion that it would be a good thing if at the first meeting of this Committee I were able to announce that I had a considerable sum of money already collected or promised. I had the idea that it might be possible to find nine other members to subscribe with myself £100 each, and that I should be able to announce: "Here is £1,000 to start this fund, and the rest of the profession has got to make up £1,500 or £2,000." I believe nearly a year ago I asked one member of the profession if he would be one of the ten; that was Dr. Clement Stephenson, of Newcastle, and he said he would. (Applause.) Since that time Mr. Salusbury Price, who is well known to

all members here, has promised his £100. (Applause.) There is £300 towards the thousand. One other gentleman, although he could not see his way to be one of the ten, promised £50, namely Mr. Inglis McCallum, of Edinburgh, and when one remembers Mr. McCallum's unprecedented generosity to the profession in other directions one cannot say that this subscription is not a handsome one. (Applause.) But I want it to be clearly understood that these subscriptions are absolutely conditional. Speaking for myself, I am not going to give anything like £100 unless nine other members give the same sum, and all the others who make the promise have made it on this condition. I am not going to ask across this table any member here to be one of the ten, but what I am now saying will, I dare say, be reported, at least in substance, and I want to make it an appeal to anybody in the profession who feels that he could be one of the ten without injustice to his own interests—I want to appeal to him to become one of the ten. It has been suggested to me by a gentleman who is not here that a hundred should agree to give £10. Now to suggest this as an alternative to the other scheme is to misunderstand my idea. I do not accept that as an alternative suggestion. I quite agree that somebody might try to induce a hundred members to give £10 each. The idea has my hearty good wishes, but it is not an alternative to my own one.

The point I want to refer to next is a rather important one. One of the bye-laws governing these International Veterinary Congresses is to the effect that any funds remaining over from one congress has to be handed over to the Organising Committee of the next Congress. It so happens that there is nothing to be handed over to us, and we do not desire to have any surplus after the London Congress. With a view to preventing such a thing it would be well to have a guarantee fund distinct from the amount unconditionally subscribed, and in asking nine other members to join with me in raising £1000 I have suggested to them that half of the sum should go to form a guarantee fund, and that the remaining half should be subscribed unconditionally.

That, gentlemen, is how the thing stands with regard to the raising of funds. I should like to suggest in that connection that an account be opened immediately with a bank, and that all sums subscribed towards the expenses of the Congress be paid into this bank in the joint names of Mr. Garnett and some other member whom this meeting will nominate, and that all disbursements should be by cheque signed by these two gentlemen. I think that would be a businesslike proceeding, and it has Mr. Garnett's approval. Will you suggest the name of a gentleman to act as co-trustee?

The name of Mr. R. Roberts was proposed, and it was decided that Mr. Roberts and Mr. Garnett be appointed Joint Trustees of the Fund.

Mr. BANHAM: Could you increase the number of men who are to be asked to subscribe the £1000?

The CHAIRMAN: I have no objection to getting ten who would give £50 as well. It may happen that it will be difficult to get another seven men to give £100. But I quite expect within a week to have the sums offered to me—otherwise I shall be very much disappointed.

Mr. LAWSON: May I ask if the members in other countries were as liberal as you expect the veterinary profession of this country to be? You are asking us now for a very large sum. We are not a very wealthy profession, and I know myself all over the country that the profession is not in a good position at the present moment, especially as they have other things to face in the next few years. I think yours is a very liberal offer, and all the others must be thanked. There are a great number in the profession who are not so wealthy as yourself, and others who may subscribe £10 or £20, but you are more likely to get £10 or £20 than those who

will be able to give £100. There may be a few, but I am speaking for the majority of the profession.

The CHAIRMAN: I hope nobody imagines that my appeal is general. I am very well aware that my appeal goes over the heads of two thousand nine hundred and fifty of the three thousand members in this country, and I should be ashamed to ask any of those men to put up £100. Perhaps Mr. Lawson is right in thinking there are not seven members remaining in the profession who could afford to subscribe £100, but that is not my opinion.

Prof. WOODRUFF: May I ask if there is any possibility of dividing your funds, the money raised, into that purely for entertainment, and that purely for the business part of the Congress.

The CHAIRMAN: Impossible, and very undesirable.

Mr. ABSON: Assuming we have £5000, how much of that amount do you propose to put on one side a guarantee fund?

The CHAIRMAN: I think very likely £500 would be a sufficient reserve.

Mr. BARRETT: May I ask what period you expect to elapse before we start spending?

The CHAIRMAN: The Secretary will have only small expenses during the next two years.

Mr. BARRETT: Would it not be well if members were asked to pay an annual subscription? Those who might not be able to afford it in a lump sum?

The CHAIRMAN: If some men are willing to give three sums of two guineas rather than a single sum of six guineas, our Treasurer will no doubt be glad to receive promises of future payments as well as present payments. We might begin to canvass immediately, and the subscriptions could be paid annually.

Mr. BARRETT: I raised the point that at the present time you don't require a large sum of money. It is not required immediately.

The CHAIRMAN: It is true that the whole of the money is not required immediately, but we should remember the old proverb "A bird in the hand is worth two in the bush."

Mr. ALMOND: How do you propose to get in the money?

The CHAIRMAN: By each of you subscribing in the first instance, and then attacking anybody you meet anywhere with "Have you subscribed to the funds for the International Veterinary Congress?"

Mr. ALMOND: I would suggest that a good many people should be elected to the Committee. There are a certain number of members who like to have something for their money. The mere honour of being on the Committee may help to open their purse strings.

The CHAIRMAN: I think it would be necessary to the sake of appearance and fashion. A horse that was limit such election to those subscribing £10. Otherwise the Committee might become unwieldy. In any event we shall have to consider the advisability of appointing an Executive Committee.

Mr. WHARAM: Bearing on this matter I might mention that some of the Veterinary Medical Associations are already moving. The Council of the Yorkshire V.M.A. the other day recommended to the Society that they should pay a sum, or put by a sum, of £10 10s. a year for three years. It will be passed next Friday at their summer meeting.

The CHAIRMAN: We hope the various Societies will give us annual subscriptions, if possible, for the three years.

Mr. HUNTING: I should like to propose that the collection of the money be by donations and annual subscriptions, and that all donors of £10 10s. should be members of the Organising Committee.

Mr. GOOCH: That would be unfair to subscribers, if only those who could afford ten guineas could be on the Committee.

The CHAIRMAN: We can put any man on the Committee we choose, but the payment of a subscription of ten guineas might give a man the right to become a member of the Committee.

This was agreed to, and after some informal discussion,

Mr. J. S. LLOYD: We shall soon be appealing for funds, but a large number of the members of the veterinary profession know very little about the Veterinary Congress. I suggest that it would be a good thing in issuing an appeal for funds if you were to ask the Secretary or any other member to give a short history of the International Veterinary Congresses, and send it out with the appeal. You would then get subscriptions from the rank and file who would otherwise perhaps not be inclined to pay.

There is another matter, in regard to the Local Veterinary Societies. Probably a number of the Veterinary Societies could club together to get up an entertainment. For instance the Congress might be invited to Cheshire and see the Duke of Westminster's seat at Eaton Hall, and perhaps to Tring, where are to be found perhaps the best stock in England. Also probably our Scotch friends might invite the Congress to Edinburgh.

Mr. STOCKMAN: I have the pleasure to announce that Mr. Roberts, on behalf of his firm, has agreed to subscribe £100 in three years. He was too modest to make the announcement himself. (Applause).

The CHAIRMAN: With regard to what Mr. Lloyd has just said, it will no doubt have to be considered whether the Secretary should not draw up an appeal and issue it to the whole of the members of the profession. We shall have to keep clamouring at the profession during the whole of the three years. On the whole I think that as a start we should endeavour to collect as much as possible by individual influence.

The meeting then terminated.

THE NATIONAL VETERINARY BENEVOLENT AND MUTUAL DEFENCE SOCIETY.

The annual meeting was held at the Grand Hotel, Aytoun Street, Manchester, on Thursday, April 6th. W. A. Taylor, Esq., President in the chair. Present: Messrs. Woods, Somers, Elam, Clarkson, Sampson, Stent, Wolstenholme, Edwards, Hughes, Hopkin, Weston, and G. H. Locke.

The PRESIDENT, in his opening remarks, said that there was practically nothing new to mention, and that he thought, considering the usefulness of the Society, that it was strange that the number of members was not greater.

HON. SECRETARY'S REPORT.

Since our last annual meeting the Society has been continuing its useful work. The Council has had to deal with three defence cases: one being amicably settled, another abandoned and costs recovered, the third is pending, but appears likely to be dropped.

We have had about the usual number of benevolent cases to deal with, and financial assistance given and very gratefully acknowledged by the unfortunate applicants.

Our membership still remains about the same, not increasing, as one would expect for such a deserving organisation. During the past year we have enrolled ten new members, one resignation has been accepted, six members have died, and five names have been deleted for arrears, according to resolution passed at the last annual meeting, leaving a total of 257, Dec. 31st, 1910.

The HON. TREASURER, in his report, stated that the sum of £20 5s. had been spent in the defence of members, and the sum of £75 had been disbursed from the Benevolent Fund to nine recipients. The total amount of arrears December 31, 1910, was £26 15s. 6d., of which the sum of £14 14s. has been abandoned, and the sum of £12 1s. 6d. has been carried forward.

The balance sheet of both branches of the Society was received and adopted. The balance at Bankers, Dec. 31, 1910, was: Defence branch, £826, 4s. 1d.; Benevolent branch, £354 1s. Invested funds, £4,800. Total funds in both branches being £5,980 5s. 1d.

The Hon. Treasurer intimated that a Mersey Docks and Harbour Board Bond and two Mortgages with the Salford Corporation had fallen out this year, and would require to be re-invested. This matter was referred to Council.

OFFICERS FOR 1911.

Trustees. Messrs. A. W. Mason, T. Hopkin, R. S. Reynolds, and E. Faulkner.

President. Mr. W. A. Taylor, Manchester.

Vice-President. Mr. W. Woods, Wigan.

Hon. Treasurer. Mr. J. Wolstenholme, Quay Street, Manchester.

Hon. Secretary. Mr. G. H. Locke, Grosvenor Street, Oxford Road, Manchester.

Council. Messrs. A. Butters, London; J. Clarkson, Garforth, nr. Leeds; J. W. Coe, Stoke-on-Trent; E. Faulkner, Tedbar Hopkin, and A. Lawson, Manchester; A. W. Mason and F. W. Somers, Leeds; J. McKinna, Huddersfield; W. Shipley, Great Yarmouth; Henry Sumner, Liverpool; and R. C. Trigger, Newcastle-under-Lyme.

Auditors. Messrs. Litton, Pownall and Co., and J. H. Wright, M.R.C.V.S., Manchester.

* As Diseased or Exposed to Infection

Conviction for Docking.

At Tower Bridge before Mr. Cecil Chapman, William Hartley, jam manufacturer, of Green Wharf, Tower Bridge Road, was summoned for causing two horses to be ill-treated; his horsekeeper, John E. Miller, was summoned for ill-treating the horses. Mr. Stuart Bevan was instructed for the Royal Society for the Prevention of Cruelty to Animals; Mr. Curtis Bennett was for the defendants.

Inspector Allcorn, Royal Society for the Prevention of Cruelty to Animals, said that at the stables of Mr. Hartley he saw two horses, recently docked, Miller stating that this was done to smarten their appearance and strengthen their backs. Mr. Hartley, whom he saw later, said he knew that docking was done, but did not

know it was not allowed. He supplied Miller with the docking irons.

Cross-examined, the witness said most horses in London were docked. These horses were in good condition, and the operation had been properly performed.

Mr. William Hunting, F.R.C.V.S., an ex-President of the Royal College of Veterinary Surgeons, said that docking was not necessary either for the comfort or well-being of horses. It was only justifiable in a case where a horse was a leader of a team, or was attached to a tip-cart. The operation did not strengthen the back of the animal.

In cross-examination, the witness agreed that nine out of ten horses were docked, but in answer to Mr. Bevan, he said he had never seen a racehorse docked, and before

the South African War it was not the practice to buy docked horses for the Army.

Mr. Alexander Piesse, M.R.C.V.S., gave it as his opinion that docking was absolutely unnecessary, and extremely painful to the animal. It did not make driving less dangerous; it was, in fact, shaping the horse to the cart, and not the cart to the horse.

In cross-examination, the witness said there was a certain amount of danger of reins getting under long tails.

Mr. Curtis Bennett said that Mr. Hartley had fifty horses, and they were all docked. He did not know that it was wrong to dock them, and thought it was safer for driving about London streets to use docked horses. This was the first case of its kind in London, and counsel urged that as the docking was reasonably necessary there could be no conviction.

Mr. Cecil Chapman said there was nothing in the evidence to show that the practice was reasonably necessary. The docking of horses was founded upon ignorance, but, having become a custom, it prevailed long after the ignorance had been exposed. It was really done for the sake of appearance and fashion. A horse that was docked really did look smarter, and might fetch more money at a sale, but to enhance its value by inflicting pain upon a horse was not justifiable. Mr. Hartley rightly took upon himself the responsibility of his servant's acts, because he had followed the custom of docking in the ordinary old-fashioned way. There was nothing against him individually, but in order to mark the importance of the case he would be fined £3, with £3 3s. costs. Miller was ordered to pay 2s. costs. —*Daily Telegraph*.

THE CAUSE OF SWINE FEVER.

Sir,

I, no doubt in common with many other members of the profession, was very pleased to read in to-day's *Record* that the cause of this devastating disease in swine had been discovered.

It is very satisfactory to know that the discovery was made by a country practitioner, after this scourge has baffled such eminent men in this country, the Continent and the United States where the disease is more prevalent.

I was always given to understand that the disease was caused by an ultra-visible organism, but after the confident manner in which Mr. Upton speaks of his discovery I am compelled to accept his decision. No doubt shortly Mr. Upton will give us full details in the veterinary journals of the arduous research work which he has undertaken in the dark years preceding the dawn of his brilliant achievement. Yours faithfully,

JAS. T. ANGWIN.

Arundel, July 8.

Sir,

In your last issue of *The Record* appears a letter by Mr. George Upton on the cause of "swine fever," which explains to my entire satisfaction how the police are in a position to diagnose swine fever.

They can evidently see the minute strongyles and are thus able to recognise the disease at a glance, but I am rather of the opinion that they occasionally make mistakes; and that Mr. Upton is one of the reasons why it has baffled every attempt to eradicate it.—Yours truly,

E. MARRISON.

THE OBJECTORS TO THE AMENDMENT BILL.

Sir,

The editorial note which you appended to Mr. Dyer's latest utterance will probably have struck the majority of the profession as a quite sufficient comment upon it. For the benefit of the minority, however—and for the especial benefit of Mr. Dyer and his allies—I ask leave to emphasise two points.

The first is that my question to Mr. Dyer and his col-

leagues on the "Executive Committee" still remains unanswered. I still ask what evidence they can give us that there are 900 members opposed to the Bill—they have given us none yet. The mere statement that Mr. Dyer has seen "some 600 signed letters from opposers of the Bill" (dates of letters and date of inspection alike unspecified) is no evidence at all of the number of members opposed to it now. A large number of names were once enrolled in opposition to the Bill in its earliest form—in other words, to another and a very different measure; but I deny the existence of 900 opponents of the present Bill in the profession, and in this connection I again ask why the opponents of the measure have let the last two elections of Council pass without presenting one candidate; it is very significant that Mr. Dyer has not even pretended to answer that question.

Now be it noted that, according to Mr. Dyer, I have "an evil mind." (He says that I am an "evil mind," but I suppose that that is his method of affirming that I possess one—these opponents of the Bill put the English language to strange uses at times, do they not?) Well, having an evil mind, I naturally feel keen delight in pressing this second point of mine. Mr. Dyer affects to treat me and the greater portion of my letter with "silent contempt," and, of course, he is at perfect liberty to assume that lofty attitude, though I may remark that indulgence in querulous abuse is not exactly consistent with it. But Mr. Dyer *does* attempt to answer me upon the one point of the existence of 900 opponents of the Bill, and so far fails to give me any answer at all. Taking every word of that sentence which he makes such ado about italicising as correct, there is nothing in it to show that there are *nine* men in the profession still opposed to the Bill—let alone 900.

My second point is this—that as Mr. Dyer has once tried, through the medium of your journal, to convince the profession that there are still 900 opponents of the Bill, he at least has put himself out of the position to treat any such doubting Thomas as myself with "silent contempt." His four co-signatories have either not deigned or not dared to justify to the profession a statement which they and he did not hesitate to make of the profession in order to influence men who knew nothing about it. Probably it would have been more politic on Mr. Dyer's part to have followed their example; but, having attempted such justification, he is bound to succeed or fail in the eyes of the "honest men" to whom he appeals—and he has certainly not succeeded yet. This is more than a question of *opinion*—of course Mr. Dyer has a right to his own opinions, and he has aired them in your pages till now uncriticised by me, for I did not think that their exposition was likely to do any harm. But now we are upon a question of *fact*—Mr. Dyer has committed himself to a statement of fact which there is nothing in the history of the profession to support, and much to negative.

Perhaps Mr. Dyer will also tell us something about the goings on of this wonderful "Committee," which is said to be much bigger than it has ever proved itself to be. What are its terms of membership? and is any subscription exacted from the members in order to conduct the "very strong opposition," or is the name of any individual who has sent the Committee a post-card and forgotten all about it in a week put on the books and allowed to remain there for ever and ever?—How on earth is the whole blessed concern managed and kept going? Who is its Chairman? and did it ever hold a general meeting? and by what selective process were the five illustrious "members of Executive Committee" appointed? and, once again, *why has the Committee given up electioneering?*

What sort of "strong opposition to the Bill" has it been offering during the past two years or so, or has it offered any at all in that period? Can Mr. Dyer, indeed, give us any evidence whatever of the Committee's vitality between the months of June, 1909, when its octet of candidates came to grief at the polls, and May, 1911, when its reprehensible little circular was surreptitiously issued to M.P.'s? And are those hundreds of letters in Mr. Hurndall's possession really open to a complete examination—complete enough to ascertain the date of each correspondent's latest communication—or would only a judiciously selected batch be submitted to inspection, and the rest be merely flourished in the face of the seeker after "the TRUTH," and then

boxed up again? In asking these questions, I am very mindful of the phrase "Not loving the light," which Mr. Dyer thinks fit to apply to me. Considering the veil that shrouds the machinations of this curious "Committee," I think he might better have applied it elsewhere.

And finally, as I hope and expect that Mr. Dyer will make another effort to demonstrate the present existence of his 900 opponents of the Bill, I suggest that his four brethren in the faith that there are such ought to help him in the task. He has worked very hard already, and written many letters against the Bill; but I am not sure that some of them have ever done anything against it except put their names at the bottom of that dreadful circular. By so doing they made themselves equally responsible with him for its contents, and for them to keep silence upon it will give evil-minded scribes the chance of saying that they are ashamed of it. And besides—Mr. Dyer says that your space is valuable, and I agree; but I suppose that there are still some members who have not yet made up their minds regarding the Bill itself, and could your space be better occupied than by matter likely to help them to a decision? I can conceive of nothing more conducive to that desirable end than an attempt by the champions and spokesmen of the opposition—champions of the very best *quality* that the opposition can produce—to convince us of their own *quantity*. The last column in your current issue is instructive and suggestive in this respect, and I hope to see future ones even more so.—Yours faithfully,

"MEPHISTOPHELES."

THE LIMITS OF DIAGNOSIS—SYMPTOMS.

Sir,

There is no denying the fact that many points in Mr. Wallis Hoare's article are true, but I really think he too lightly assumes that the very many practitioners who must plead guilty to this charge of "lightning diagnosis" are so self-satisfied as to be quite pleased with their performances.

No practitioner, however eminent, who has been long in practice, can truthfully say that he is not often troubled with serious misgivings after having "satisfied a client." Although we all may condemn dogmatic assertions, still there really is much to say in favour of those men who seem to be gifted with intuition, or at least, certainly can draw conclusions quicker than their less fortunate fellows.

Most of us soon learn that although we try to study and treat cases scientifically there is no assurance that we shall gain in public estimation, in truth the opposite much oftener, leads to this goal, and only proves that those men whom we often refer to as "clever dogs" are just the ones who possess a good deal of that most useful commodity *common sense*. Further, they are appreciated, and I think rightly so, by those men who "sleep" with their stock, and on whom all of us must rely for a more or less truthful statement about our patients. Symptoms are what our profession has really to rely on for diagnosis, and considering this, is it really very shameful if we admit we are often grievously at fault? When a student in my final, one of those so-called "practical men" was asked (during a grind) for the symptoms of pneumonia in the horse, his answer was—Uneasiness, pawing, lying down quietly, looking round at his sides, hurried breathing, attempting to stale, with often inactivity of the bowels. I am well satisfied now that this man, who was then assistant to a very clever town practitioner, did not at all merit the ridicule he then called forth, and that these well known symptoms do not always mean so-called colic. The following are no isolated cases but are typical of some "facers" one receives now and again.

A farmer called one night and asked me to see a horse, and here is the history. The horse started in the morning being uneasy, lying down and getting up again, crouching, pawing, looking round, straddling with hurried breathing. They gave him some gin and ginger and sheeted him up, but he was no better, so would I go. A very ordinary case this (although always grave) so took the usual remedies to treat a bowel complaint. I need not enter into the treatment adopted further than to say that I always give a

physic ball if a bowel case hangs fire, and I believe I am as successful as my neighbours in treating these cases. Of course I had examined the horse, considered it some bowel complaint, and was treating it accordingly. Nothing had passed the bowels since morning and the rectum was empty. Next day same symptoms, but fluid coming from the nostrils, and he died that night, never having shown at any time violent pain. On post-mortem the stomach and bowels showed not the slightest trace of disease, but the lungs were black and friable and showed very extensive pleuritic effusions.

A hunter, after a hard run, stopped on the road with feet propped out, head extended, nostrils dilated, and breathing laboured. When I saw him, after everything had been done to persuade him to move to a stable a short distance away, the pulse could not be felt, he seemed glued to the spot, and there was stertorous breathing. Diagnosis: Congestion of lungs; and expected him falling over dead any minute. Had to be shoved all the way to the stable, where he now stood with his head pressed into a corner, and being no better in two days he was destroyed. Post-mortem: A tumour in the brain, with all the other organs apparently healthy.

J. KERR CALDERWOOD, M.R.C.V.S.

Sir,

It is with considerable reluctance that I have again to ask you for the favour of some space in your correspondence columns. I am mindful of the fact that with your permission I shall continue the consideration of the above subject, with reference to cattle and dogs, on a future occasion, hence my present remarks in reply to Mr. Mayall will be brief, and I hope relevant to the points at issue.

If the faculty of speech attributed to Balaam's ass were possessed by animals in the present day, I am quite sure it is not on the subject of diagnosis that they would convene with "man, proud man," "most ignorant when he is most assured," far more likely they would plead for a cessation of the continuous drugging to which they are so often subjected by the "ledger" therapists and orthodox believers in medicines.

I am pleased to hear that in some parts of the Empire the owners of animals are taking some interest in morbid anatomy; as, however, they are hardly likely to expend much in the way of fees in the pursuance of this knowledge, I fear that the number of autopsies held will not be augmented to any extent.

I confess that I fail to see the point in Mr. Mayall's story so far as he believes it to apply to the natural or spontaneous recovery of cases. Even those outside the ranks of the "therapeutic nihilists" do believe in the *Vis medicatrix nature*.

I can assure Mr. Mayall that it is not only in out-of-the-way quarters of the world that ignorance flourishes. I have met with striking examples of it in various parts, so far as belief in the virtues of drugs and the infallibility of certain practitioners is concerned.

There many stockowners, intelligent in every other respect, who believe firmly in the fetish of "worm in the tail" and kindred affections. Even lately I met a qualified veterinary surgeon who expressed his belief in this fetish, and argued that "when the 'worm' was removed the cow recovered." No doubt his argument was as feasible as those who believe that a similar result should be attributed to the medicine administered.

I am pleased to find my views are supported by "Momparsa." He is evidently an accurate observer, and possesses that "wise scepticism" which is essential to progress.

What an advantage it would be to the profession if some of those who have reached the "cakes and ale" stage could be persuaded to admit the limits of their skill? We can only hope that there are many more juniors who hold the views of "Momparsa," if so, they can show a worthy example to those of the seniors whose only interest in life is to listen to the "jingling of the shekels and the lowing of the oxen."—Yours, etc.,

E. WALLIS HOARE.

Is a compound of aluminium silicate, glycerin, boric acid, menthol, thymol, oil of eucalyptus, and ammonium iodide, forming a convenient and efficient antiphlogistic application superior to poultices, fomentations, etc.

THERMOFUGE

Does not require the repeated changes which poultices necessitate and, unlike them, it does not afford a medium for the growth of disease germs.

THERMOFUGE

Reduces swelling and capillary congestion, allays pain, soreness and throbbing, and has an alterative effect upon inflamed glands. It softens indurated tissues, reduces tense tumefactions, and restores tone to strained tendons.

THERMOFUGE

Is a thick paste which is spread over the affected area (or applied on linen) and covered with oiled silk retained in position by a bandage.

Supplied in Tins of $\frac{1}{4}$, $\frac{1}{2}$, 1, 5 and 10 pounds.

Extra Strong, Yellow.

6/6 per doz. 72/- per gross.

Sole Proprietors—

HARKNESS, BEAUMONT & CO.,

Wholesale Chemists,

EDINBURGH.

Veterinary Surgeons have for long keenly felt the want of something which could be used with good results as a Uterine Antiseptic and which at the same time could be quickly and easily administered. After many trials, and with the kind co-operation of some able Veterinary Surgeons of great experience in parturition cases, we have succeeded in producing

a Pessary made with a non-oily base which does its work efficiently and at the same time is non-irritant—in fact, soothing in its effect. They are of great use in parturition in cows or mares; and if administered immediately after parturition they will keep the Uterus clean and healthy, and prevent the after-birth becoming foul.

Veterinary Surgeons in various parts have highly recommended them, and there is an increasing demand for both kinds.

Customers are requested when ordering to state which kind they prefer.

A RECENT UNSOLICITED TESTIMONIAL.

AINSWORTH WILSON, ESQ., F.R.C.V.S.,
writes:—

"I have used the Saloform Pessaries supplied by Messrs. Harkness, Beaumont & Co., of Edinburgh, with good results in various diseases of the genital organs, both in mares and cows, more especially after parturition. They are particularly useful in retention of the afterbirth, with septic complications. It is often impossible to attend more than once a day to irrigate the uterus; in such cases it is good practice to leave one or two of the "extra strong" pessaries *in situ*. I have found them an excellent substitute for Iodoform and other well known non-irritating antiseptics. I feel justified in recommending them to the profession.

Witham, Essex.

THE VETERINARY RECORD

A Weekly Journal for the Profession.

EDITED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1202.

JULY 22, 1911.

VOL. XXIV.

THE INTERNATIONAL VETERINARY CONGRESS OF 1914.

The report of the meeting of the Organising Committee of the International Veterinary Congress, which we published last week, is worthy the attention of every member. The utterances which fell from Sir John M'Fadyean in the chair will show how heavy a responsibility is to be cast upon the profession.

Much future work, of very varied nature, lies before the Organising Committee when the time comes for arranging the programme of the Congress. But the sole work at present is the collection of funds, and all members will recognise how formidable a task this will be. No financial undertaking of such magnitude has ever been attempted by the profession in this country—and it is from the profession in this country that the money must come. If a sum sufficient to ensure the success of the Congress is to be raised, it can only be by the united efforts of the profession, and the sources from which the money may come are roughly divisible into three. In two of these directions there is already evidence of activity; the third has not yet been tested at all.

First we mention the local professional Societies. Each Society should subscribe what it can annually to the fund, and we believe that most, if not all, will do so—some are moving in this direction already. The Societies will do their duty, but they are few in number, and some are not strong, so that only a comparatively small proportion of the sum required can be expected from them.

Next come the few individual members who are able to afford large subscriptions, and here again activity is evident. The £50 donation of Mr. McCallum, and the support already extended to Sir John M'Fadyean's project of raising £1,000 by ten £100 subscriptions, augur an abundant assistance to the fund from the wealthier members of the profession. A large proportion of the ultimate total will come from them—but not the major part, nor is it fair to ask them to bear this.

Finally, we have the smaller individual subscriptions of the rank and file of the profession—men who cannot be expected to subscribe heavily, but nearly all of whom could afford a little. It is upon the action of these men that the success of the fund really depends. Of course, if every member able to subscribe even half-a-guinea annually were also

willing to do so, there would be no need for large subscriptions at all. And if even a quarter of our number were willing to follow the precept and example of Sir John M'Fadyean, and "subscribe as far as their means allow," the success of the fund would be assured. The whole amount required only represents about £1 per member, and we have ample time to raise it. The one thing necessary is a sufficiency of general interest, and a sufficient number of subscriptions—not necessarily large ones individually—from the rank and file of the profession.

The Treasurer, Mr. F. W. Garnett, Dalegarth, Windermere, will gladly receive all monies, which may take the form either of donations or annual subscriptions. A small annual subscription will probably be the more convenient method to men of limited means; but it should be commenced at once.

Two points should be borne in mind. Large as the sum seems, it can be easily raised, if a sufficient number of us will subscribe a little. And, if a sum adequate for the purpose is not raised, the cause of International veterinary co-operation will sustain a serious check, the whole reproach for which will justly lie with the members of the profession in the United Kingdom.

GUTTURAL POUCH DISEASE.

Sequel to a case reported in June 3rd issue of The Veterinary Record.

Although it is truly said that it is as important to record failure as success, it is with a somewhat heavy sense of disappointment that it becomes a duty to relate a fatal sequel to an apparently successful operation. As stated in the concluding lines of the first report, the animal was being conditioned for return to duty. The date of discharge from hospital had been actually fixed when a careful examination revealed a more than normal fullness of the left guttural pouch. The order for discharge was consequently cancelled and the animal kept under close observation. At the end of a week all doubt was at an end, a relapse had occurred.

Operation was postponed till, symptoms of dyspnoea commencing to be evident, it was decided upon. The procedure differed in no essential detail from that described in the first operation, but definite location of structures was rendered more difficult by the new tissue scar formation. An incredibly large quantity of food *débris* and pus of a very fetid nature was evacuated. The pouch was washed out with Tinct. iodi. solution. The dys-

St Anthony Card
St Anthony

phagia after the operation was even greater than on the first occasion, but hope was not abandoned till on the third day gangrenous pneumonia supervened. To this the animal speedily succumbed.

The post-mortem examination revealed dilated eustachian tubes—the initial cause of the disease, and an abnormally long downward and backward extension of the left guttural pouch, the pocket-like end of which was behind, and on a level with, the first ring of the trachea. In this *cul-de-sac* pus was found. The walls of the pouch were of course thickened. The apices of both lungs were in an advanced state of gangrenous pneumonia. There was considerable pharyngitis, and purulent foci were found in the surrounding connective tissue of that region.

The main conclusion arrived at as the result of the post-mortem was that the possibility of cure would have been greater had it been possible to open up for some extent of its length the downward prolongation of the hypertrophied guttural pouch, and thus ensure a more satisfactory dependent orifice. For anatomical reasons, however, this would have been most difficult.

It appears certain that, after the first operation, there still remained at the bottom of the pouch a little pus, which, on the closure of the operation wound, acted as a starting point for fresh infection. The opening into the pouch made through Viborg's triangle was some two inches or more above its lowest extremity. It should be made clear that the fatal relapse only occurred in connection with the left guttural pouch. The first operation appeared to have been successful in the case of the right pouch.

WAKEFIELD RAINEY, Capt. A.V.C.

Bloemfontein, S.A. June 24.

A CASE OF ROUND CELLED SARCOMA.

The subject of the accompanying photograph was a middle aged van mare, owned by a poor man and used for fruit transport.

The numerous subcutaneous growths were said by the owner to have made their appearance suddenly, and an examination of the animal disclosed no apparent health disturbance. Although in rather poor condition the temperature was normal, and the appetite regularly good.

The case was treated by me for about a month in a rather uninteresting manner, and with no resulting impression.

After the application of the mallein test a course of mercurial iodides were tried, and then as no improvement was obtained one of the growths was excised and sent to the Royal Veterinary College for microscopical examination. Sir John M'Fadyen very kindly reported it to be a case of "round celled sarcoma."

Upon receipt of this information the mare was at once destroyed and the carcase cremated.

I regret that for a variety of reasons no post-mortem examination was made. I also regret that

the history and description of what, to me, was an unusual case should be somewhat barren, but I think the photograph compensates in some measure for the lack of written detail.

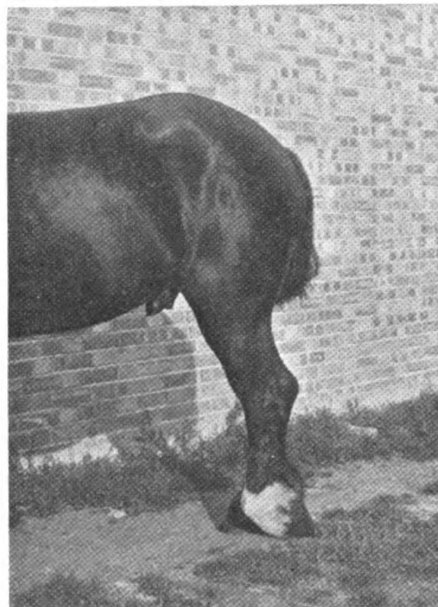

E. ALFRED WEST, F.R.C.V.S.

London, W.C.

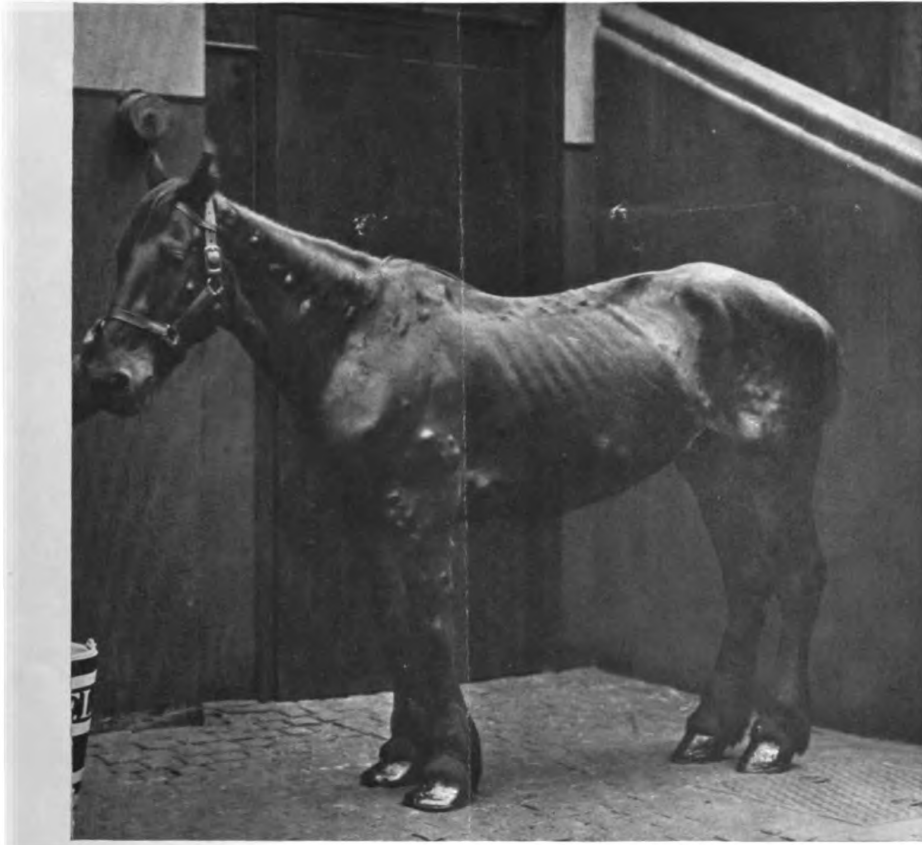

AN INDICATION IN STIFLE LAMENESS.

By A. E. BAYLEY, M.R.C.V.S.

It seems to be the fashion nowadays in some quarters to be rather too pessimistic; and to describe a certain symptom or gait as being *diagnostic* of lameness due to a particular lesion is to court the stricture that "fools rush in where angels fear to tread!" Despite this risk, however, and in the hope that it may interest a few of your readers, I venture to enclose a photo which is intended to depict an attitude *characteristic* of a condition of the stifle joint causing troublesome lameness.

It will be observed that there is extreme "knuckling" of the *fetlock* joint, so much so that the end of the cannon bone very nearly rests upon the ground, and that the angle which normally exists at the flexure of the hock joint is nearly obliterated, causing the limb as a whole to approach the perpendicular. Once seen one can readily differentiate this peculiarity from the perfectly normal attitude—which it reminds one of—assumed by the horse when standing at ease; the chief difference being that in the latter position the angle referred to instead of being more obtuse has become less than a right angle. In addition there is in old standing cases a somewhat distended and tense condition of the bursa, the result of chronic inflammation of the synovial apparatus of the stifle joint,

SARCOMA IN THE HORSE.

To illustrate note by Mr. E. Alfred West, F.R.C.V.S.

My early and painful experience of this condition was obtained when practising chiefly amongst horses employed in omnibus work on the London streets. I assume the lesion is brought about by the enormous strain to which the muscles of the hind limb are constantly subjected by the repeated attempts to start the 'bus after it has been allowed to come to a dead stop on a greasy condition of the asphalt.

The animal, the subject of this photo, is a light vanner. He is of the highly strung, intemperate variety which "jumps into collar" when starting to pull his load, and cannot be restrained from doing more than his share of the work.

The treatment consisted of pyro puncturing the stifle accompanied by a smart blister, and followed by a prolonged rest at grass. That is now twelve months ago, and as there has been no recurrence of the lameness since the horse resumed work some months ago one is hopeful that a cure has been effected.

I confess, until my experience with the omnibus horse, that I used to be sceptical as to the existence of lamenesses that could be ascribed purely and simply to the stifle. Now, however, I think one is justified in asserting with every confidence that what one has tried to illustrate and to describe here is of quite common occurrence in animals performing certain kinds of work and who are of a certain temperament. At any rate, I claim that there is quite as much justification for regarding the above symptom or attitude as diagnostic of stifle trouble as there is in attributing "pointing" and some of the other so-called classical symptoms as certain indications of navicular and other diseases.

CASE OF EQUINE TUBERCULOSIS.

On the 10th ult., I was requested to attend a four-year-old unbroken draught filly which had been grazing with other animals and thriving well, when, without any obvious cause, her breathing was noticed to be abnormally accelerated, so she was taken up from grass and placed in a loose box. She was fractious, and had never been handled, so I only made a cursory examination, as I deemed it undesirable to use means of restraint. Her respirations were about twenty per minute and were accompanied with a double expiratory effort, slight nasal discharge, appetite fair; the fæces were examined for parasites, but none could be found. I provisionally diagnosed the case as pneumonia.

She was fed on nourishing food in which medicaments were given, and milk and oatmeal gruel were added. Despite a fair appetite she very rapidly emaciated, and the respirations became more laboured. On auscultating the chest no crepitation was detected, but the respiratory murmur was increased over the whole area of the lungs. The pulse was full and quickened, the visible mucous membranes slightly injected, and she emitted a very occasional suppressed cough. Her temperature was not taken, on account of the temper she evinced.

Her appetite gradually failed, diarrhoea supervened, and she died on the 23rd ult.

On post-mortem examination, I found that the mesenteric lymphatic glands were very much enlarged and contained puriform fluid. The stomach and bowels were small and nearly empty, and an ulcer was noticed in the large intestine. The spleen contained several small yellowish nodules. The liver and kidneys appeared to be healthy. The lungs were enlarged and heavy, and on section presented the appearance of grey hepatization. I obtained smears from the lungs, spleen, and mesenteric glands, and stained them with Ziehl's solution, and on microscopic examination immense numbers of Koch's bacilli were visible on the slide prepared from the mesenteric gland, and in smaller quantity from the spleen and lungs. Sir J. M'Fadyean, to whom I sent specimens, kindly confirmed the diagnosis.

I had a case of tuberculosis in a three-year-old filly on the same farm several years ago, and in that animal the organs affected were the spleen and the mammary gland.

Chertsey.

"PERITONEAL WASHINGS" IN THE PREPARATION OF ANTI-RINDERPEST SERUM.

Major F. S. H. Baldrey has published (*Journal of Tropical Veterinary Science*) an article upon the method of augmenting the amount of virulent material for the production of anti-rinderpest serum by means of "peritoneal washings" or "peritoneal fluid." This method was first inaugurated by workers in the Phillipine Islands, but has since been further developed at Muktesar. Some of its results were irregular at first, and Major Baldrey's article is largely devoted to an exposition of experiments which were undertaken to definitely estimate its value.

The technique is comparatively simple. Control animals which are to provide inoculable material receive an intra-peritoneal injection (varying in quantity with the animal's weight) of a .5 per cent. sterile solution of potassium citrate at a temperature about 27° C. One hour later, the animal is bled to death; and the fluid is collected from the peritoneal cavity immediately after death. About 50 per cent. of the amount injected is recovered; and this increases the material for hyper-immunising purposes to more than 50 per cent. without any increased expenditure in animals.

The advantage of this method is obvious; and but for its employment the short supply of Hill cattle would have prevented the Muktesar Laboratory from turning out a quantity of serum even approaching the amount it actually did produce last year. Major Baldrey's researches, however, have increased the existing knowledge of the action of the peritoneal fluid, and are also indirectly suggestive regarding the nature of anti-rinderpest serum itself.

Briefly, Major Baldrey's main conclusions are—that the method of employing "peritoneal washings" to augment the amount of inoculable virulent material is a good one; that it produces an anti-rinderpest serum of a high value, though less potent than that produced by blood inoculation; that in comparison with serum from blood inoculations it is of greater value in the less susceptible Plains animals than in the highly susceptible Hill cattle; and that its reaction is produced principally by a toxin, which is rapidly formed under the vital influence of the peritoneal cavity. The inoculation of very large doses, however, is not advisable in Indian cattle, as peritoneal fluid is not absorbed so well subcutaneously as is blood, and also—if given in very large doses—has an extremely caustic effect upon the tissues, and may cause death from acute toxæmia.

Indirectly the research has yielded evidence supporting the view that anti-rinderpest serum is an anti-toxin, and experiments have been commenced in this direction which will be reported in due course. It is possible, also, that further experiments in diluting the peritoneal fluid or mixing it with blood may result in improving upon the present practice of this new inoculation method. Major Baldrey's present research has certainly yielded a more accurate estimate of its value, so far as Indian cattle are concerned.

ABSTRACTS FROM FOREIGN JOURNALS.

CHRONIC INFECTIOUS CATARRH IN CATTLE.

The disease described by Johne in 1895, and later attributed to an intestinal infection by the bacillus of avian tuberculosis, and then demonstrated by Bang, to have no connection with tuberculosis at all, is frequent in Prussia, and affects cattle at grass as well as housed.

It is a true cowshed disease, and is transmitted by the dung of affected animals, in which the characteristic acid-fast bacillus is recoverable as well as in the intestines. Food, water, milk, and pasture, if infected, become so from the dung.

Cows three to six years old most frequently fall victims to the disease, young animals escape or very rarely become infected. The period following the birth of the first or second calf is the most favourable for the appearance of the disease. Young calves apparently become immune through the milk of an affected dam.

The disease runs a long course, and may lie dormant a long time before an animal shows signs of being affected.

The symptoms are diminution and eventual loss of milk, diarrhoea and excessive thirst, progressive wasting in spite of good feeding.

The leading symptoms are the wasting, the constant diarrhoea with very liquid dung, and as the cow lies down much more and longer than usual she

becomes much soiled by it. There is no alteration of temperature as a rule. The dung is very liquid, foetid, and covered with gas bubbles and mucus; the animal as a rule is bright, and lively and retains her appetite, and an exact diagnosis is difficult.

Treatment is not a success, and the beast cannot be fattened. Animals die in about three months as a rule sometimes they linger on for six.

There is a diphtheritic deposit on the stomach and small bowels, and red patches in the colon and cæcum. The ileum and cæcum are generally affected, the duodenum and rectum but rarely. The mesenteric glands are much enlarged and softened. There is an infiltration of giant, epithelioid and round cells into the submucosa, there is no degeneration or caseification, and the invasion extends slowly from the cortex into the struma of the glands.

The bacillus is shorter and broader than the tubercle bacillus, with which it is often confused, and it is found in masses in the epithelial cells, and in the dung. It is very difficult to induce it to grow on ordinary culture media.

By the infiltration into the submucosa, the villi lose their structure and physiological functional activity, hence the wasting and diarrhoea. The usual experimental animals are not infected by the usual means, but calves readily respond to infective material from the glands, either in food or injected.

The disease is differentiated from tubercle by the non-reaction to tuberculin, although there is a reaction with avian tuberculin; by the absence of caseification in the glands. From parasitic invasion by the absence of worms or ova in the dung. Also by the loss of milk and characteristic diarrhoea and wasting.

Prophylaxis consists in keeping non-affected animals away from the dung of those affected, and early slaughter of the affected ones: isolation, and thorough disinfection of premises.

A passive immunity of an unsatisfactory character has been obtained with extracts of bacilli, but a more satisfactory active immunity is obtained from sterilised bacilli extracted from the mesenteric glands.

In Italy the disease has not been noted in native cattle but is found in Dutch cattle imported; it is frequent in Holland.—*Vet. Ber. & Clin. Vet.*

RABIES.

By international agreement, cases of rabies occurring within ten kilometers of the border in Belgium or Germany are reciprocally reported to the other country.—*La Clin. Vet.*

PERIODIC OPHTHALMIA IN CATTLE.

Outbreaks of periodic ophthalmia are reported to occur after cattle are put on to young trifolium, and a child who rubbed its eye after assisting to dress one of the affected beasts developed a similar disease. The cases readily yield to treatment.—*Ber. Vet.*

F. E. P.

SENILE ATROPHY OF THE BONES OF THE DOG'S SKULL.

The lesions of the senile atrophy of the human skeleton are well known, but little is yet certainly known of these osseous changes in the domestic animals. Prof. Dr. Pick, of Berlin, contributes (*Berliner Klin. Wochenschr.*) a note upon this condition in the dog.

In the skull of a collie, which had died at the age of eleven years, Pick was able to demonstrate especially well-marked lesions of senile atrophy, which had affected all the bones of the skull. All these bones appeared extremely thin (in parts as thin as paper) or perforated and apparently "worm eaten" by deep pits and channels internally and superficially. Alterations in the form of the skull or traces of inflammatory osteophytes were completely absent. The teeth were loose and showed small deep pits and corrosion at their roots, so that many appeared manifestly coarsely porous.

Pick, in collaboration with Dr. Schmey, a veterinary surgeon, has now gone further into the question of osseous atrophy in the old dogs, and has been able to demonstrate the process in all its stages in a complete series of macerated skulls and other bones. There is, therefore, a typical form of senile osseous atrophy in the dog, which affects the skull alone, or at least preponderates in that region, reaches an excessive degree of development, and may involve all the bones of the skull. It is a simple senile atrophy.—*Berliner Tier. Woch.*

THE CONFORMATION OF THE DACHSHUND AS A CAUSE OF PARAPLEGIA.

Complete or incomplete paraplegia of the hindquarters is rather common in dachshunds, and Jakob considers (*Münchener Tierärztliche Wochenschrift*) that the predisposing cause is the excessive length of the body in this species. The last dorsal and the lumbar vertebrae are not sufficiently supported by the limbs in running and jumping, and in consequence of this, bilateral wrenching of the peripheral nerves (lumbar plexus, great sciatic, and sympathetic) are easily possible. These injuries become manifest by the appearance of sensory (hyper-æsthesia) and motor disturbances; and the functions of the intestine and the other abdominal organs may also be disturbed.

All circumstances which may bring about a too intensive alteration in position of the vertebral column must be considered directly exciting causes. Among these are clumsy jumping, extreme turning sideways, too violent curvature of the back during tenesmus, violent coition, and so forth. A well-nourished condition of the body increases the predisposition to the affection, as also does the advance of age.—(*Berliner Tier. Woch.*)

(Is paralysis of the hindquarters really commoner in long-bodied breeds than in others? I doubt it, but an attempt to prove or disprove the idea, even with abundant statistics, would expose the investigator to many risks of undetected error.—**TRANSL.**)

W. R. C.

PYOCYANEUS INFECTION IN DOGS AND ITS SIMILARITY TO RABIES.

By Maj. W. F. HARVEY, I.M.S., and Capt. R. MARKHAM CARTER, I.M.S., and HUGH W. ACTON, I.M.S.

Several variations from typical rabies have been described both in animals and in man. These have received such names "chronic rabies," "abortive rabies," and so on. The question of the possible spontaneous cure of rabies has also received attention. Some authors in discussing these conditions have suggested the possibility of incorrect diagnosis and the idea of a bacterial causation. We do not directly deal with any one of the conditions mentioned above, but our own experience leads us to believe that the bacterial causation hypothesis is worthy of attention. In this paper we consider that we make out something of a case for the existence of a *B. pyocyaneus* infection occurring naturally in dogs, and that such infection may, both as regards symptoms produced and tests applied, lead to confusion with rabies. Of course, we are aware that *B. pyocyaneus* is a very ubiquitous organism, and we must therefore leave to our readers the judgment as to whether contamination has or has not been excluded in the case which we present to them. The diagnosis of rabies by animal experiment is often the only test at our disposal, and may be summed up as depending on the subdural inoculation in a rabbit of an emulsion of the brain of the suspected animal with subsequent onset of paralysis, and death within a given period. Only exceptionally do we add to this a bacteriological examination. The result of such an examination in rabies should, of course, be negative. We think we are right in saying that if the cultivation from brain substance showed sterility in forty-eight or seventy-two hours, it would be assumed that the tissue was sterile, and that the experiment went to confirm the diagnosis. We shall see that some of our cultivations from brain substance did not develop growths of *B. pyocyaneus* for more than seventy-two hours after inoculation. The point is an important one. Further, if subpassages are made by subdural inoculation, and the same train of paralytic symptoms leading to death appears as in the original experiment, the diagnosis of rabies would be considered as completely established. But we show that the brains of animals which have succumbed to subdural inoculation, and which have yielded pure cultures of *B. pyocyaneus*, are capable of giving rise to the same symptoms as in the original when reinoculated after the manner for rabies diagnosis. We have carried the experiment to as many as eleven subpassages in one case. It must be remembered that, as part of the evidence leading to a diagnosis of rabies, we must include the suspicion attaching to the condition of the animal or brain of the animal which was brought or sent to the institute on account of the fear that the animal was rabid.

The disease produced in rabbits and guinea-pigs by *B. pyocyaneus* is well known, and has been described. As far as we know, it has not been specially described as a disease naturally occurring in dogs. The points of differentiation from rabies of the disease are:

1. Absence of Negri bodies from the hippocampus major of the animal suspected of rabies, if a microscopical examination is available. The absence of Negri bodies from the brain of the animal inoculated is not absolutely to be relied upon. We have been able to show scanty Negri body formation in the brains of guinea-pigs inoculated with pure cultures of *B. pyocyaneus*.*

2. The paralysis induced in the inoculated rabbit is somewhat different in character, although not necessarily in incubation period, from that of rabies. The description of the disease in rabbits as given by E. Macé† will bring

out both the points of resemblance to conditions which have been called rabid and also the points of difference. Pyocyanus disease, he says, takes different forms, according to the character and the quantity of the virus introduced into the organism, and also according to the state of the animal. The affection may manifest itself very acutely in less than twenty-four hours, less acutely in three to four days, or it may develop in chronic fashion and last even for several months. In the rapid forms the chief symptoms are readiness to stumble, loss of appetite, somnolence, and often at the end convulsions. There are, besides, fever, diarrhoea, albuminuria. The animal emaciates and falls into a cachectic state. Finally, there appears in certain cases motor paralysis of a type which is quite characteristic. These paralyzes do not supervene immediately after inoculation. There is a rather long period of incubation—twenty days to two months. The hinder extremities are the first attacked, either simultaneously or successively or singly. At the autopsy no lesions, either of muscles, nerves, or nerve centres, are to be found. The diagnosis is easily made clinically or bacteriologically. The above description refers to animals inoculated either subcutaneously, intra-peritoneally or intravenously. Our cases were those of dogs which apparently had developed the disease naturally, or rabbits which, having been inoculated subdurally in the test for rabies, developed the chronic cachectic form (otherwise described as consumptive rabies), or were animals subdurally inoculated with brain material containing *B. pyocyanus*, and which developed the acuter form of the malady. The symptoms in the animal observed by us corresponded accurately with those described by Macé. The paralysis in particular is very typical, and may easily be distinguished from that due to rabies when attention is drawn to it. Diarrhoea was not a prominent symptom in our animals. The paralysis in its final stages could not be distinguished from that of rabies.

3. Cultures from heart's blood or liver or brain give a pure growth of *B. pyocyanus*. This we were able to obtain in all our cases.

Other dogs than those mentioned were examined—animals to which no suspicion of rabies attached—and no growth of *B. pyocyanus* occurred. Nor did cultivations made from heart's blood, liver, or brain of test animals dying from undoubted rabies ever show growth of *B. pyocyanus*.

In many of the cases, in order to exclude the possibility of agonal infection, the animals were not allowed to live until death, but were chloroformed in the later stages of the disease. The *B. pyocyanus*, we found, can, when contained in tissue, resist the action of pure glycerine for a time. It can thereafter give rise to "pyocyanus disease" in rabbits subdurally inoculated, although with a long incubation period and more manifest wasting than when unglycerinated cerebral tissue is used.

The case which led up to the search for and experimentation with *B. pyocyanus* is instructive in its details. It was as follows: A patient came to the institute for treatment, after having been licked on abrasions by his own dog. The dog died under suspicion of rabies. (Some time before the development of the disease this dog had pups which were about six weeks old.) During our patient's stay under treatment one of these pups developed a sickness and was brought to us for inspection. The animal was very weak and could not stand, and was detained under observation. Before death it exhibited spasmodic movements of the limbs. The symptoms were not exactly characteristic of rabies, but did not exclude the possibility, and, when taken in conjunction with the history, were at least suggestive of that disease. The brain of the pup was removed, and was used in a series of dilutions (subdural inoculation) in an experiment designed to determine the connection

between length of incubation and degree of dilution. That is to say, we assumed that the disease was rabies, and had no suspicion of any other. The actual experiment was instituted because it is comparatively seldom that at this institute fresh brains can be obtained, and we did not wish to lose the opportunity thus afforded us. Six rabbits were inoculated subdurally with varying dilutions. All six developed paralysis and died. It was the nature of the paralysis which raised our suspicion that the disease was not rabies, and which led to the making of cultures from brain and from heart's blood. The heart's blood culture gave a growth of *B. pyocyanus*, but the culture made from the brain did not do so at all. This last fact indicated that the bacilli were at least very sparse in the cerebral tissue. That they were there, however, was shown by the subpassage experiments which followed. The following are the details of our cases:

CASE I.

Puppy belonging to Captain L., a patient. Mother of pup died of suspected rabies. Puppy fell sick, could not stand, and died twenty-four hours later with convulsions. Six rabbits inoculated with emulsion of fresh puppy's brain. All six developed in the course of sixteen to twenty-days paresis of the hinder extremities and died a few days later.

Rabbit 2 (passage), inoculated subdurally from one of the six rabbits, developed the same disease. The heart's blood gave a culture of *B. pyocyanus*, whilst the culture from brain was sterile.

Rabbit 3, inoculated from Rabbit 2 October 16th, 1909, showed tremor October 30th; paralysis in hind quarters October 31st, and died November 2nd. Heart's blood gave growth of *B. pyocyanus*. Brain showed sterile.

Rabbit 4, inoculated from Rabbit 3 November 2nd, 1909, showed paralysis November 23rd, and died November 25th. Heart's blood showed *B. pyocyanus*. Brain sterile.

This series was continued. The broth tubes inoculated from the brain might have given a growth had this been kept long enough. The subpassages gave quite clear evidence that the brain tissue was also infected, as later cultivations showed, with *B. pyocyanus*. In the later subpassages *B. pyocyanus* was recovered also from the brain. Rabbit 11—the last of the series, inoculated February 17th, 1910—showed paralysis on March 3rd, and was killed with chloroform on that date. The heart's blood on culture gave a green scum on the surface of the broth in twenty-four hours, whilst the culture from the brain gave the same in forty-eight hours. Coloration of the broth itself followed.

A portion of the brain of Rabbit 11 was placed in pure glycerine, and kept there for three days at room temperature.

Rabbit 12, inoculated with glycerinated brain of rabbit 11, March 7th, 1910, did not show any paresis until May 11th. The animal had undergone considerable emaciation. Paralysis nearly complete May 13th; killed May 16th. Heart's blood gave a greenish-brown scum on the broth culture on May 17th, which by May 18th was a thick green growth. Brain culture showed a definite green tinge of the fluid and growth on May 19th. Thus *B. pyocyanus* lying in cerebral tissue can withstand the sterilizing action of pure glycerine for three days and give rise after that period to symptoms and death resembling those of what has been called consumptive rabies.

CASE II.

Dog of Lient. S., brought to Institute on December 24th, 1909. The dog presented an appearance which might have been that of the last stage of rabies. It lay on its side quite unable to move and saliva was dribbling from its mouth. The dog was chloroformed. The hippocampus major showed no Negri bodies.

Rabbit 1, inoculated subdurally from dog's brain showed total paralysis and death on the third day. Heart's blood gave culture of *B. pyocyaneus* in twenty-four hours; brain in forty-eight hours.

Rabbit 2, subinoculated from Rabbit 1, January 29th, 1910, showed marked paresis on February 7th, and was killed with chloroform on February 8th. The paresis in this case came on earlier than in the previous cases. Heart's blood gave culture of *B. pyocyaneus* in forty-eight hours; brain in ninety-six hours.

Rabbit 3, done from Rabbit 2, February 8th, 1910, showed paresis, February 15th, complete paralysis, February 16th, on which date it was killed. Cultural results the same as in Rabbit 2. In this series we find a very distinct shortening of the incubation period.

Rabbit 4, subinoculated, February 16th, 1910; paresis, February 23rd; marked, February 24th; killed, Feb. 26th. Cultures from both heart's blood and brain gave green scum in forty-eight hours. The brain of Rabbit 4 was kept in glycerine at room temperature three days, and Rabbit 5, inoculated with this glycerinated material, developed symptoms of wasting and paralysis, and died seventy-two days after inoculation.

CASE III.

A dog was sent to the Institute from a near station. On arrival the dog was in a distressed condition, and ropy saliva was hanging from its mouth. The dog was not aggressive, and did not look altogether like a case of rabies. It died the same night (January 25th, 1910), and the body was placed on ice.

Guinea-pig 1, inoculated with emulsion of dog's brain, January 26th, 1910; paresis, February 15th; death, February 16th. Cultures from heart's blood and brain gave growth of *B. pyocyaneus*.

Guinea-pig 2, from Guinea-pig 1, February 16th, 1910; was observed to be unwell, February 27th; showed no definite paresis, but died emaciated, March 9th. Heart's blood gave culture of *B. pyocyaneus* in twenty-four hours; brain in forty-eight hours.

CASE IV.

A dog had bitten, unprovoked, three persons. The persons came to the Institute for treatment, bringing the dog with them. The dog was kept under observation. It did not show any special signs of rabies. Any symptoms shown were rather those of viciousness. It did, however, on one occasion dart at a stick passed in between the bars of its cage. As the dog remained alive for over ten days the persons bitten were not treated. This dog was kept some time. It became emaciated and developed diarrhoea, and was chloroformed. A heart's blood culture, taken this time from the dog's heart itself, gave a marked *pyocyaneus* culture in forty-eight hours. The case is important in connection with histories of unprovoked attacks and the value attached to this in the diagnosis of rabies.

These cases all agree most remarkably in the finding of *B. pyocyaneus* in the heart's blood and brain. Some of the animals were not allowed to die, but were chloroformed before death. An agonal infection is thus excluded. Nevertheless, *B. pyocyaneus* is a widely distributed organism in nature. But the invariability of the finding in the cases of animals under suspicion of rabies, and the absence of the particular organism in cases where rabies either was not in question or was quite definite, suggested that here we were dealing with a disease occurring naturally in dogs, and which may simulate, say, either rabies or distemper. We decided, however, not to publish the above four cases, or to raise the question of diseases liable to be confounded with rabies, until we should confirm our findings with another such case. This we have in Case V. As the case is an important one from the point of view of decisions as to

the necessity or non-necessity of treatment we give it somewhat fully.

CASE V.

The dog in question had licked two people and bitten two. The two who were bitten received their injuries in the course of an attempt to administer medicine. All four persons came to the Institute—a distance of some 300 or 400 miles—for treatment. Only the two bitten were treated. The circumstances of the cases were these:

A change was noticed in the quality of the bark. The animal showed some perversion of appetite—ate earth. It was able to drink milk, and showed no particular irritability. The dog was sent to a veterinary subordinate, and as it showed weakness of the extremities also, it was shot as rabid.

The brain arrived in glycerine, and was changed into fresh 50 per cent. glycerine September 14th, 1910. An emulsion of glycerinated brain was inoculated subdurally into a rabbit on September 15th. The animal remained well till October 15th, when it showed a certain amount of wasting. The hind limbs were noticed to be slightly paralysed on October 20th, and it died on October 26th, with both hind limbs paralysed.

Post-mortem examination.—Brain somewhat injected, liver engorged, spleen normal, bladder distended. The hippocampus major showed no Negri bodies. Culture from brain sterile. A portion of the brain of this rabbit was placed in glycerine for twenty-four hours and inoculated subdurally into a second rabbit, October 27th, 1910. Wasting showed itself on November 10th, and paralysis of the hind legs on October 12th. The animal when fully paralysed was chloroformed. *Post-mortem:* Engorged liver; slight congestion of vessels of pia, arachnoid; distended bladder. Subcultures were made from heart's blood, liver and brain.

The culture from the liver alone showed a growth, and that again was *B. pyocyaneus*.

The brain was kept for twenty-four hours in glycerine, and a third subpassage carried out on November 15th, 1910. Paralysis of the hind legs appeared on November 26th, and the animal died on December 1st. *B. pyocyaneus* was recovered from the brain, heart, blood, and liver. The subpassage was done up to the seventh, and every time the *B. pyocyaneus* was recovered from the heart's blood.

REMARKS.

1. *B. pyocyaneus*, although a common and widely-distributed organism, is not such a common contamination or such a common agonal infection as to account for facts here set forth. Agonal infection is negated by the fact that many of the animals were not allowed to die naturally, but were put out of existence by chloroform.

2. Other observers have mentioned the possibility of the occurrence of microbial diseases simulating rabies, but have not, so far as we know, incriminated *B. pyocyaneus*.

3. One author (Beck †) has been able to reproduce a disease by subdural inoculation in a case of distemper, but was not successful in carrying the subpassages further. Other observers have been able to make several subpassages with distemper virus.

4. The confirmation of the facts here set forth, and their bearing on cases of reputed cure of rabies, and such conditions as chronic rabies, abortive rabies, and consumptive rabies, must be left to further investigation.

SOUTH DURHAM AND NORTH YORKSHIRE VETERINARY MEDICAL ASSOCIATION.

A special meeting was held in the Imperial Hotel, Darlington, on Friday, July 7th. The President, Mr. C. R. Dudgeon, Sunderland, in the chair. There were also present Messrs. P. Snaith, A. C. Forbes, Bishop Auckland; E. H. Pratt, Northallerton; W. N. Dobbing, C. G. Hill and J. H. Taylor, Darlington. Mr. J. M. Walker, West Hartlepool, was present as a visitor.

Apologies for non-attendance were received from Messrs. W. Awde, W. H. Blackburn, and H. Peele.

Mr. J. M. WALKER, M.R.C.V.S., was proposed for membership by Mr. Hill, and seconded by Mr. Forbes.

It was proposed by Mr. Hill, and seconded by Mr. Pratt, and unanimously carried, that the proposed excursion of the members and friends of the Association to Middleton-in-Teesdale and Langdon Beck on July 28th take place, and that members do their best to get their friends to accompany them.

The PRESIDENT stated that he believed that the present meeting was the outcome of something which he mentioned in his Presidential address as to the desirability of the members working together in unity with reference to fees which were paid by Insurance Companies to members of the profession for examination of animals, as in his opinion these fees ought to be refused. Therefore this meeting was called "for the purpose of discussing professional fees, and the desirability of some uniform scale of charge being drawn up." He took the strongest objection to the fees offered by Insurance Companies, and absolutely refused to work for any such fees. The fees paid by Councils were hardly worth working for, and he had more than once almost decided to throw up his appointment as an Inspector.

When his address was discussed by the members he was surprised to learn that the fee paid for castration in the neighbourhood of Darlington was so small as five shillings, and he would certainly not castrate a colt for such a fee.

On the other hand circumstances had to be considered, and where in a district such a fee was the usual one it was of course obvious that if one did not do the operation another would, unless some uniform scale was agreed upon.

He regretted that there was such a small response to the circular, which had been sent out both to members and non-members in the district, and it showed the great apathy of the profession when members of it would not try and come together and try and get better fees, and it really looked as if they did not care one little bit.

Mr. FORBES thought that all would like to see the fees raised, but the question was, How to do it? In his district there were many castrators, not veterinary surgeons, who were operating in quite a skilful way for 5/-, and the question was, Were they to accept this fee or lose work? He always charged 5/- if he was paid at the time of the operation, but if he booked it he charged 10/6. He did not undertake any work for Insurance companies unless he was in the neighbourhood, then sometimes if the number of animals to examine was considerable, it was not a long job; it was money soon obtained if one was driving past the place in the ordinary course of one's rounds.

Mr. SNAITH said that some years ago he took part in a discussion as regards fees paid by the Durham County Council, and he was then prepared to "go on strike" for better fees. He sent a letter to all the Inspectors of the County Council, but very few replied and nothing could consequently be done. When one had to spend sometimes a whole day, say in investigating an outbreak of sheep scab, and make a microscopical examination in

each suspected case, for the fee of one guinea and their fare, he thought one was certainly not paid a sufficient fee. It seemed to him a strange state of affairs when the County Council were spending such a vast amount of money annually on education that they should refuse to pay a man a decent fee who had spent a large sum of his own money in educating himself for his profession. The whole thing to his mind was simply absurd. Castration ought to be never less in his opinion than 10/6, and this was the fee charged in his district when first he commenced practice there, but another veterinary surgeon commenced to charge 5/-, and so the fee got reduced.

Mr. DOBBING had not much to add to what the previous speakers had said, and agreed entirely with the views they had expressed. He feared, however, that unless we were unanimous as a profession things would just remain as they were. He would welcome something being done with reference to County Council work, and would support any proposal to increase the fees paid by County Councils to their Inspectors.

Mr. PRATT said that at the last meeting he suggested that a circular should be sent to all the members of the profession in the neighbourhood, whether members of the Association or not. This had been done, and he thought that they, as an Association, had shown a desire to do something to increase the fees. There was such a poor response to-day that so far as he could see we were perfectly helpless in the matter.

Mr. HILL had to regret the utter apathy of the profession with reference to the subject under discussion, and in his opinion, having such a poor muster after calling such a meeting, was a disgrace to the profession. Members of it would not try and improve their position. He never castrated a colt under 10/6, and would far sooner castrate ten colts at 10/6 than twenty at 5/-. Far better stop at home and castrate cats at 2/6 than colts at 5/-. He always charged 5/- for docking, but recently when he did this operation and asked 5/- for it, he was told by his client that his fee was too high, for he could get it done for 1/-. [A Voice: Let him get it done]. All the calving cases ought to be 10/6 in his opinion, and more if the case was very difficult. He was surprised to see the prices charged by quack medicine vendors for some of their preparations, and found that 6/- per dozen was charged for cough powders, for instance, when many veterinary surgeons charged less. He strongly objected to veterinary surgeons leaving cards at shoeing forges, and having medicine chests in public-houses.

Mr. WALKER, speaking as an outsider, not being a member of the Association, agreed with what had been said by previous speakers. He might say that he always charged 10/6 for castration, and whereas when he first commenced practice in his district he only castrated ten colts the first year, this year he had done 40, in spite of his opposition charging only 5s. If he was called out at night he always charged double fee, particularly in those cases where the animal had been ill all day and they came at bed-time for him. He was perfectly certain that no agreement was possible in his district with his fellow practitioner, but in spite of that he intended to keep his prices up, and he thought his experience as regards his castration justified it.

Mr. TAYLOR said he was very much disappointed at the small attendance at the meeting. He had sent out 29 circulars, and only eight veterinary surgeons had turned up, which, in his opinion, did not seem to favour any uniform scale of charge being drawn up, and being agreed upon. He thought, however, that if the Inspectors of the County Councils drew up a letter putting their case clearly before the Executive Committee that something might be done.

The PRESIDENT, in summing up, said that the discussion had only gone to prove that what he had said in his

address was true. His advice was to try and get to know your neighbours, do away with petty jealousies, put your heads together and try and get better fees, above all to value your own services, and one could not have a better illustration of this latter remark than in the case of Mr. Walker, who although he charged as much again as his opposition did for castration, was actually castrating more colts year by year.

J. H. TAYLOR, Hon. Sec. (*pro tem.*)

CAPE OF GOOD HOPE VETERINARY MEDICAL SOCIETY.

An ordinary general meeting was held at the Central Hotel, Cape Town, on Thursday, May 18th. Present: Messrs. R. W. Dixon (Vice-president), J. Forrest, J. W. Crowhurst, E. Fern, and R. Paine (Hon. Treasurer and Secretary).

The minutes of the former meeting were considered and passed.

Correspondence from the Natal V.M.A. and the Transvaal V.M.A. was considered, and the question of a meeting of delegates of the various South African Associations *re* amalgamation of Societies was fully discussed.

Mr. CROWHURST proposed that the Secretary be instructed to inform the Transvaal V.M.A. that "This Association is in favour of the meeting of delegates from the various South African Associations in Cape Town to consider the question of amalgamation, and suggests that two delegates be appointed to represent each Association, also that sufficient notice of the meeting be given for a meeting of each Association to be called for the appointment of the said delegates."

Mr. E. FERN seconded the proposal, which was unanimously carried.

ANNUAL GENERAL MEETING.

This followed the ordinary meeting, and the same members were present.

The minutes of the former meeting were considered and passed.

The Council's annual report was received:—

Your Council begs to lay before you its annual report for the year 1910-11.

The fourth annual general meeting was held on May 13th, 1910, since which date five general and six Council meetings have been conducted.

The principal points considered during this period are:—

1. Veterinary Surgeons Ordinance. Although some delay has possibly been caused, your Council is glad to be able to report that some of the points raised by the Cape of Good Hope V.M.S. have now been carried, and that it is free to act in agreement with the other Associations on the subject.

2. Amalgamation of Societies. Your Council has framed a scheme for an amalgamated British South African Association, and is unable to agree with the South African Association scheme proposed by another Association, but they hope to meet representatives of the other Associations and to come to a unanimous decision shortly.

3. Registration of Farriers in Natal.

4. The Council were advised of the formation of a Natal Veterinary Medical Association early in the year.

Regarding the payment of dues, the members have now been excused the payment for the past two years, but naturally certain expenses have been incurred by the Association during this period, and the Council trusts that its members will remember the favours already received when the next payment is due.

Two members have been excluded for non-payment of arrears, and the two members in arrear have since paid up to date, so that all members are now in good standing. One new member has joined.

The financial statement is practically the same as at the beginning of the year, viz., £139 11s. 11d. as compared with £133 11s. 8d. upon May 13th, 1910.

Members who sometimes grumble (usually inwardly) at the work achieved, are asked to remember that it is often only at great personal inconvenience that members are able to attend the different meetings, and that besides the transmission of reports of meetings (general and Council), and notices of meetings etc., during the past twelve months a matter of over 140 letters have been dealt with or despatched.

ELECTION OF OFFICERS.

President.—Mr. J. D. Borthwick.

Vice-President.—Mr. R. W. Dixon.

Hon. Treasurer and Secretary.—Mr. R. Paine.

Council.—Messrs. W. Robertson, J. Forrest, J. W. Crowhurst, J. Buck, J. W. Freer, and the representative of the A.V.C. stationed in Capetown.

CASH STATEMENT, MAY 14, 1910, to MAY, 1911.

Receipts.

Subscriptions	...	£11 11 0
Savings bank (withdrawal)	...	5 0
		£16 11 0

Payments.

Savings bank (deposit)	...	£4 4 0
Typing	...	8 5 0
Postage, Stationery, etc.	...	1 5 11
Cash in hand	...	2 16 11
		£16 11 0

It was resolved that no annual subscription be called in for the coming financial year.

The following subjects of professional interest were then discussed: Parasitic gastro-enteritis in cattle, Superpurgation in horses, Paralysis of horses, the use of aspirin in paralysis in dogs.

No further business being brought forward the meeting terminated.

Royal College of Veterinary Surgeons.

EXAMINATIONS IN LONDON.

At the meeting of the Board of Examiners held in London on July 14th for the Written, and on July 18th and 19th for the Oral and Practical Examinations, the following gentlemen passed their Third Examination:

Mr. V. Boyle
O. S. Broadhurst *
K. J. S. Dowland
J. Facer
E. S. Farbrother
J. Going
S. J. Gilbert *
W. P. Hamlyn *
A. C. Holl *
P. Howard

Mr. R. H. Knowles *
S. W. Marriott
W. F. Morton
E. B. Reynolds *
J. M. Smith
P. R. Viljoen
U. W. F. Walker
R. T. Davis
S. H. L. Woods

The following passed their Second Examination :

Mr. W. A. Austin	Mr. W. B. Howe
C. E. W. Bryan	V. J. Hare *
D. Blyth *	G. C. Harding
C. Davenport	H. Hicks *
H. W. Dawes †	W. H. Priston
G. van de W. De Kock *	J. M. L. Penhale *
G. O. R. Grey *	J. Southall
A. Hoskin *	W. L. Sheffield
R. C. G. Hancock	A. R. Symthe *

The following passed their First Examination :

Mr. C. O. A. Anderson	Mr. G. H. Melck
A. Bayly	C. Rammell
R. M. Bamford	H. C. Rockett
H. H. Curson	T. S. Roberts
H. S. Cockburn	P. S. Sparling
H. Chown	F. H. Stainton *
R. W. D. C. Eason	J. F. D. Tutt *
E. E. Jelbart	C. H. S. Townsend
A. G. E. Lalor	W. H. Wortley †

Marked thus † passed with First Class Honours.

" * " Second "

Death from Anthrax.

At St. Pancras Mr. F. Danford Thomas held an inquest on Henry Stephen Thurston, aged 24, of Broad Lane, South Tottenham, laboratory attendant at the Medical School at University College Hospital, who died in that institution from anthrax poisoning.

Dr. Marshall Cowell, Senior Resident Medical Officer, said the first intimation he had of deceased's illness was on Thursday, 6th inst., when he saw a boil on right side of his neck about the size of a shilling. The day before the dangerous character of the boil had been suspected

and a microscopical examination revealed anthrax. An immediate operation was performed in the course of an hour or two. After the operation the deceased's temperature dropped, and in a day or two he appeared to be out of danger. On Sunday his temperature began to rise again, and serum treatment was resorted to, but death ensued on Wednesday, 12th inst., from blood poisoning from anthrax bacilli.

Dr. Francis Hugo Theale, Lecturer on Bacteriology at the University College Hospital School, said he was in charge of the vaccine department. It was deceased's duty to clean up material after the students. The cause of infection in this case was that deceased must have caught hold of some tube or something which had contained the bacillus, had scratched the side of his neck, and rubbed the poison in. Such a thing ought never to have happened, every precaution being taken. Witness had about thirty students working at the School, and it was three weeks since he had lectures on these particular organisms. The students would study them for a week, and in a few days the organisms became innocuous. He could not say how it happened, unless one of the students had carelessly allowed some of the organisms to get on the outside of the tube.

The Coroner: Considering the number of laboratories about, I think it is wonderful there are not more cases.

Witness remarked that these organisms became so mild that last Christmas he injected some into two mice, and they did not die. Deceased was in rather a bad state of health at the time. The dangerous organism of glanders and farcy were all killed before they were handed round to the students. This was the only live organism handed round. He had to train medical officers, and, to become acquainted with these organisms, they must handle them.

A verdict of death from misadventure was returned. —*The Times*.

NOTE.—The figures for the Current Year are approximate only.

* As Diseased or Exposed to Infection

Foot-and-Mouth Disease at Rye.

The Chief Veterinary Officer of the Board of Agriculture visited Road End Farm, Udimore, near Rye, Sussex, on Tuesday, and confirmed the outbreak of foot-and-mouth disease discovered on Monday.

The animals attacked comprised three cows and five calves (one dead) in the yard at the farm, and a cow and calf on marshland on the farm. The stock on Road End Farm consist of six cows, nine calves, 26 yearlings and two-year-old cattle, and 1,712 sheep and lambs, and of the sheep 29 were in the infected yard and 41 on the infected marsh, but in neither case had the disease spread to the sheep and lambs. On an adjoining farm, which is occupied by the father of the tenant of Road End Farm, and where the latter resides there are three cows, 270 sheep, and three or four pigs, and these, as well as the stock on the healthy pastures at Road End, will be kept under close observation. The usual regulations as to the movement of animals within a radius of about 15 miles from the affected farm were put in force at once.

The proximity of the seat of infection to the Romney Marshes gives rise to apprehension locally as well as to the central authorities; at this time of the year the Romney Marshes carry thousands of cattle and tens of thousands of sheep.

The sales of sheep in the district have not yet begun, lambing being later in the Romney breed of sheep than in the Downs and other longwools, and there is still time to stamp out the disease before the heavy traffic in store and breeding stock begins.—*The Times*.

Anthrax in Central Markets, London.

The following particulars concerning a recent seizure in the Central Markets are given by Dr. Collingridge in his last report to the Sanitary Committee:—

On Wednesday, May 24th, one of your meat inspectors in the Central Meat Market, while examining some pig carcasses for tuberculosis, observed one which, in his opinion, presented lesions suggestive of anthrax. Pending a diagnosis, the carcass was carefully isolated. A microscopical examination was then made by your veterinary inspector, which revealed the presence of anthrax bacilli in considerable numbers. Subsequently his diagnosis was confirmed by the assistant pathologist of the Royal Veterinary College, and also by the veterinary inspector of the Board of Agriculture, to whom specimens were sent as required by the Anthrax Order, 1910. The usual precautionary measures were taken, and everything with which the carcass had been in contact was disinfected.

USEFULNESS OF LABORATORY.

I would point out that within fifteen minutes of the discovery of the carcass a definite diagnosis had been made and the necessary measures taken to prevent any danger from spread of the infection, thus demonstrating the value of the laboratory recently established at the Central Markets, and the advisability of having the services of a scientific advisor available for such cases. Recent investigations have shown that pathological lesions in pigs that have succumbed to anthrax may be often so slight as to escape recognition without microscopical examination.—*Meat Trades' Journal*.

Balliol College Herd.

The seventeenth catalogue of the Balliol College herd of Aberdeen-Angus cattle, founded 1880, and the property of Mr. Clement Stephenson, Balliol College Farm, Long Benton, and Sandyford Villa, Newcastle-on-Tyne, has just been issued. The new catalogue is necessitated by sales from the herd, a fresh crop of calves, and new

additions to the herd. To prevent repetition, the pedigrees have been contracted, and to facilitate references the cattle are arranged alphabetically and consecutively numbered. The herd, as already mentioned, was founded in 1880, and for many years its representatives were successful in the principal showyards of the country. The preparation of cattle for showing ceased nine years ago, and since then the herd has been kept under conditions that are as near natural as possible, spending most of their time out in the open. The herd may be seen at any time on application to Mr. Clement Stephenson at the above addresses.

Mr Burns' Milk Bill to be Introduced.

It is understood that Mr. Burns proposes shortly to introduce a Bill dealing with the milk supply. A Bill was first introduced by Mr. Burns dealing with this question in 1909. But previously to this, in 1908, the London County Council introduced a General Powers Bill with clauses for dealing with the milk supply. On March 5 in that year, on the second reading stage of the Bill in the House of Commons, Mr. Courthope moved an instruction to the Committee to strike out from the Bill all clauses dealing with the milk supply other than model milk clauses, and this was agreed to, as Mr. Burns announced that the question of the milk supply would be dealt with by the Government.

Accordingly, next year Mr. Burns presented, on May 25, his Milk and Dairies Bill, the memorandum prefixed to which was as follows:—

The main objects of this Bill are to provide for—

- (1) The more effective registration of dairies and dairymen;
- (2) The inspection of dairies and the examination of cows therein;
- (3) The prohibition of the supply of milk from a dairy where such a supply has caused or would be likely to cause infectious diseases, including Tuberculosis;
- (4) The prevention of the sale of tuberculous milk;
- (5) The regulation of the importation of milk so as to prevent danger to public health arising therefrom;
- (6) The issue of regulations for securing the supply of pure and wholesome milk;
- (7) The establishment by local authorities in populous places of milk depots for the sale of milk specially prepared for infants.

The provisions as to registration supersede the provisions as to the registration of dairies contained in the Contagious Diseases (Animals) Acts and the orders made thereunder.

The provisions as to the inspection of dairies and the prohibition of the supply of milk reproduce with amendment section 4 of the Infectious Diseases Prevention Act, 1890, section 71 of the Public Health (London) Act, 1891, and the model milk clauses incorporated in many local Acts.

The clause as to the prevention of the sale of tuberculous milk is also taken from the model milk clauses, but the scope of the enactment is somewhat extended.

The Board of Agriculture and Fisheries will in connection with this Bill issue an order under the Diseases of Animals Act, 1894, dealing with the notification of tuberculosis in cattle and the inspection, examination, detention, isolation, and slaughter of tuberculous cattle and the giving of compensation in appropriate cases.

Owing, possibly, to the course of business, the last part of the session being devoted to the great struggle over the Budget, Mr. Burns' Bill had to be withdrawn, on August 20, before it was read a second time. It was not re-introduced in the next Parliament, and therefore Mr. Courthope, Mr. Walter Long, Mr. Hayes Fisher, and others brought in, on April 13, 1910, a Milk and

Dairies Bill based on the Bill introduced in the previous year by Mr. Burns. The memorandum of this Bill was as follows :

The main objects of this Bill are to provide for :

- (1) The more effective registration of dairies and dairymen ;
- (2) The inspection of dairies and the examination of cows therein ;
- (3) The prohibition of the supply of milk from a lairy where such a supply has caused or would be likely to cause infectious diseases, including tuberculosis ;
- (4) The prevention of the sale of tuberculous milk ;
- (5) The regulation of the importation of milk so as to prevent danger to public health arising therefrom ;
- (6) The issue of regulations for securing the supply of pure and wholesome milk.

The provisions as to registration supersede the provisions as to the registration of dairies contained in the Contagious Diseases (Animals) Acts and the orders made thereunder.

The provisions as to the inspection of dairies and the prohibition of the supply of milk reproduce with amendment section 4 of the Infections Diseases (Prevention) Act, 1890, section 71 of the Public Health (London) Act, 1891, and the milk clauses incorporated in many local Acts.

The clause as to the prevention of the sale of tuberculous milk is taken from the Public Health (Scotland) Act, 1897.

The Board of Agriculture and Fisheries have prepared an order under the Diseases of Animals Act, 1894, dealing with the notification of tuberculosis in cattle and the inspection, examination, detention, isolation, and slaughter of tuberculous cattle, and the giving of compensation in appropriate cases.

On the motion for the second reading of the Bill on June 14 the debate stood adjourned, and on June 20 the order for the second reading was read and discharged and the Bill withdrawn.—*The Times*.

ANNUAL REPORT FOR THE YEAR 1910 BY THE VETERINARY INSPECTOR FOR THE CITY OF LONDON (MR. T. DUNLOP YOUNG).

During the year the approximate numbers of animals killed at the Aldgate Slaughterhouses were as follows, viz. :—

Cattle	13,760
Sheep	16,304
Calves	7,672
Total	37,736

No cases of contagious disease were observed amongst those animals.

RABIES.

No suspected cases of rabies were reported during the year. The Customs Officers reported one case of contravention of the Importation of Dogs Order, 1901, Section 9 (1) (a), but on enquiry it was found that the vessel on which the dogs were at liberty had left the Port, therefore no action was taken.

GLANDERS.

This disease is gradually being eradicated in London, due to the energetic action of the London County Council. No cases were discovered amongst horses stabled within the City.

On 17th June, a "Conference on the Extirpation of Glanders" was held at the County Hall, Spring Gardens, S.W., at which representatives of the Home Counties,

the City Corporation, and certain other Corporations adjacent to London attended. The City Corporation were represented by your Chairman and late Chairman, accompanied by the Veterinary Inspector.

The following resolutions were passed unanimously :—

- (1) That the local authority should be empowered to collect and destroy infected or suspected nosebags or other articles not easily capable of disinfection, and used in connection with glandered horses.
- (2) That the local authority in all cases should be empowered to re-test a stud after a period of a month or six weeks from the first test where there has been disease.
- (3) That the proprietors of horse repositories should be required to disclose to the local authority the name and address of any vendor of a horse if the animal is subsequently found to be glandered, together with the names and addresses of the purchasers of any other animals then sold from the same stud.
- (4) That the control of the local authority should be maintained over any horse which has been tested with mallein, so long as a definite result is not obtained from the test, provided that such control should not extend beyond a maximum period of three months.
- (5) That the Public Control Committee should be asked to convene at an early date, a further Conference with representatives of the Home Counties, the City Corporation, and other Authorities adjacent to London, with a view of considering what steps can be taken to secure greater uniformity in the administration of the Glanders Orders, and that such representatives should be limited to two for each authority, including officers.

During the inspection of horses at Custom House Quay a number of them presented suspicious symptoms of glanders and were tested with mallein ; only one animal reacted ; it was at once killed and the carcass sent to a knacker's yard, where post-mortem examination confirmed the test. The London County Council and the Board of Agriculture were notified, and I understand that as a result the Officers of the former authority discovered several other horses affected with the same disease when they visited the stables from whence the animal came. Another horse affected with "Parasitic Mange," observed at Custom House Quay, was killed, and the carcass sent to a knacker's yard, where post-mortem examination showed lesions of glanders, though the animal had not presented any clinical evidence of the disease. The London County Council Officers, on proceeding to the stable from whence the animal had come, found several other horses affected with glanders.

These cases show the benefit of inspection at the Custom House Quay, and the value of post-mortem examinations at knackers' yards.

LONDON (PARASITIC MANGE) ORDER, 1909.

This is the first full year's test of the value of this Order. That it was very necessary is proved by the number of cases dealt with. The disease appears to be very prevalent within the County of London, and has no doubt given much trouble to the officers of the London County Council, to whom I beg to express my thanks for their kind assistance in dealing with cases of contagious disease. Amongst the first cases discovered within the City, I reported for prosecution a firm of meat carriers, because it is impossible to conceive a more objectionable practice than using a rug to cover a mangy horse, and then placing the same rug around the man who handles both the meat and the horse. Unfortunately the Assistant City Solicitor, after careful consideration of the case, decided that a successful prosecution could not be obtained unless the stables in which the horses are kept are within the City area, therefore

when such cases are discovered I can only obtain the name and address of the owner and notify the local authority of that district.

The greatest trouble has been where the animals were only slightly affected with the disease, the owners maintaining that the animals were suffering from a cutaneous eruption, probably due to dirt or dietetic causes, nevertheless these are the very cases that spread the disease, as the groom pays little, if any, attention to them, and proceeds to clean other horses with the same brushes as used on the affected animals, so that only by patiently, firmly and uniformly carrying out the order will this objectionable disease be eradicated.

EXPORTATION OF HORSES.

At the beginning of the year the Board of Agriculture issued a new Order *re* this traffic, requiring all local authorities concerned to appoint a Veterinary Inspector, who should examine every horse proposed to be exported to the Netherlands and Belgium and to grant a "permit" for those found suitable for shipment. This involved extra work and considerable expense; during the short time the Order was in operation it proved very satisfactory. During the year a new Act was passed by Parliament making it the duty of the Board of Agriculture to appoint Veterinary Inspectors to examine all horses presented for shipment, and giving power to charge for so doing a sum of two shillings and sixpence per horse.

The undermentioned duties have still to be carried out by your officers, viz. :—

- (a) Supervise the shipment of horses.
- (b) Note that each horse has been certified.
- (c) Note that a "Humane Killer" is carried on board ship.

From the 1st January until 30th September, 6,402 horses were examined, and 167 or 2·6 per cent. rejected by your officers; Inspection by the Board of Agriculture Officers began on 1st October, and from that date until 31st December, 3,413 horses were examined, and 44 or 1·2 per cent. rejected, making a total for the year of 9,815 horses examined and 211 rejected. Compared with the year 1909 there are shown increases of 85 in the number of horses examined, and 66 in the number rejected.

IMPORTATION OF HORSES.

During the year 388 horses were imported into the City; those were examined on arrival and found free from disease. Compared with the year 1909, these figures show an increase of 23 horses imported.

The Crochmore Donkey Case.

The First Division of the Court of Session on Wednesday, June 28th, disposed of a reclaiming note for the defender against the Lord Ordinary's interlocutor allowing issues in the action by James Lindsay, M.R.C.V.S., 35 Whitesands, Dumfries, against John Henry Ferguson, residing at Crochmore, Irongray, for £500 damages for alleged slander. The action arose out of a certificate which the pursuer gave in reference to a donkey at Crochmore in July, 1910. In the following September the defender was prosecuted, at the instance of the Society for the Prevention of Cruelty to Animals, in connection with the donkey. Thereafter the defender raised proceedings in the Small Debt Court for damages for slander in respect that the pursuer had falsely, calumniously, and maliciously granted a false certificate as to the donkey's condition. At the instance of the pursuer that action was transferred to the Sheriff's ordinary roll, and thereupon the defender intimated that he did not intend to proceed further with the case. The pursuer said that the statements made in the small debt proceedings were false and calumnious, and the defender

did not believe them to be true, and that the defender maliciously abused the process of the court for the purpose of defaming him, and deprived him of the opportunity of clearing himself by not going to trial.

The defender denies the slander, and pleads privilege. He says he was unwilling to incur the expense which proceedings in the ordinary Sheriff roll would have involved, and, accordingly, on the case being transferred there at the pursuer's instance he withdrew from it.

Lord Cullen recently approved of the issue proposed on behalf of the pursuer and of a counter-issue for the defender, after amendment.

The defender reclaimed, and on his behalf

Mr. J. Gordon Jameson submitted that the pursuer had not stated a relevant case, and that he had no averment of malice from which the jury would be entitled to draw the inference that malice inspired the statements complained of. Counsel went on to maintain that the privilege attaching to legal proceedings in court was very high, and he challenged the pursuer's counsel to produce a single decided case which would support the case which the pursuer sought to make on malice. The second point in his submission was that even if the statements complained of had been made outside and not in an action for damages for slander they would not amount to a slander for which damages could be sought. Taking it at the very best for the pursuer, if the defender had said, outside of proceedings in court altogether, that the pursuer's certificate was untrue, there could have been no action for slander.

The Lord President said the defender had gone a good deal further than that. If he had said merely that the pursuer was wrong in his opinion, his lordship agreed there might have been very little in the case; but to say that a professional man, whose business it was to grant certificates, maliciously and falsely granted a certificate that was false was a very different and a much more serious thing. The whole sting was in the statement that the pursuer maliciously and knowingly issued a false certificate.

Without calling upon Counsel for the respondent, and after consultation, their Lordships refused the reclaiming note, with expenses.

The Lord President said there was no question that the privilege which attached to a judicial statement was a very high one, but it was not absolute privilege such as attached to what was said by a judge or by a witness, and it might be rebutted by a proper proof of malice. It was also true that a mere averment of malice would not do and that there must be facts and circumstances which were, in the opinion of the Court, facts and circumstances from which the jury might take the view that malice prompted the statement. His Lordship thought that the averments here were of that character. He did not wish to say much, because he did not wish to put himself at this stage in the position of the jury which was to hear the whole evidence. All he had got to see was whether there was something which, when proved, might affect the mind of the jurymen. He thought there was. The pursuer granted a certificate as to the condition of the donkey. That certificate merely speaks as to the actual condition of the donkey. It did not make any—naturally it was not the province of a certificate to make any—allegations as to by whose fault, if by anybody's fault, the condition of soreness on the donkey's back arose. It simply spoke as to the condition of the donkey. The condition of the donkey had, in some way or another, got wind, and the Society for the Prevention of Cruelty to Animals heard of it. A prosecution was instituted by that Society against the defender, who was acquitted. Accordingly, so far as his character in not being guilty of cruelty to animals was concerned, he was vindicated. Nobody could have any difficulty about it. The pursuer then went on to say that, having conceived an ill-will against him, the

defender proceeded to take some very curious steps in connection with parading the donkey up and down, with various legends attached to its body, which were calculated to cause annoyance to the pursuer. And then he went on to say, what was a fact, that the defender raised a small debt action of damages. Now, in that small debt action of damages he made a statement, not that the certificate as granted by the pursuer was a mistaken certificate, or even merely that it was an untrue certificate, but he said that it was a certificate maliciously given out by the pursuer in order to hurt him (the defender), and given by the pursuer when he knew that the facts in it were untrue. That, of course, was a very serious charge against a professional man. Afterwards the small debt action was abandoned. There might have been a reason for that or there might not, His Lordship was not going to say. Then the pursuer went on to say that he offered to prove that this statement in the small debt action was not really made for the purpose of getting damages at all, but was really made in order to have a convenient medium of circulating this slanderous statement which His Lordship had already mentioned—slanderous, of course, if it was untrue. It seemed to His Lordship that that was a perfectly good set of facts and circumstances from which a jury might come to the view that this was all prompted by malice. On the other hand, the defender took a counter-issue and said that the statement which he made was true, namely, that the certificate as issued was a false certificate, and knowingly false to the knowledge of the pursuer. If the defender can vindicate himself in that way there was an end to the case. On the whole matter, he thought that the Lord Ordinary was right, and that he had granted a proper issue.

Lord Johnston said he confessed he had much difficulty in this case; but, as their Lordships were both agreed with the Lord Ordinary, he did not think he was justified in differing from the opinion just delivered.

Lord Mackenzie said he was clearly of opinion that the case should be decided in the way and for the reasons which had been stated by his Lordship in the chair.—*Dumfries and Galloway Saturday Standard*.

Foot-and-Mouth—The Outbreak at Rye.

A meeting of the local sub-committee under the Contagious Diseases (Animals) Acts was held at Rye, Sussex, on Wednesday, and was attended by Messrs. R. P. P. Fulford and W. B. Hooper, Inspectors of the Board of Agriculture.

The Police Inspector (Sergeant Sinclair) reported the outbreak of foot-and-mouth disease at Road End Farm, Udmore, in the occupation of Mr. Robert P. Mair. There were three cows and five calves (one dead) affected. They were moved on to the farm in the following order:—One calf from Rye on July 6; one calf from Northiam Market on June 17; one cow and calf from the Hammonds, Udmore, on April 13; and two cows from Shorncliffe on April 6. There were altogether on the farm 41 cattle, 1,712 sheep, and four horses, which had been there for some time. There was nothing at present to show how the disease was taken to the farm. The Board of Agriculture had already taken the matter under their control.

Mr. Fulford said the Chief Veterinary Inspector of the Board visited Road End Farm, and upon his recommendation an order had been issued prohibiting the moving of live stock within a specified area. The Chief Inspector found more animals affected. Some sheep had been removed to the farm from Hammond's Farm for dipping. On the adjoining farm (Float Farm, in the occupation of Mr. Corke) 22 sheep were also suffering from the disease. They would therefore realise that the situation was very serious. All possible steps would be

taken by the Board to localise the outbreak. Meanwhile, it was hoped that all owners of dogs would keep them shut up, as they conveyed the disease.

Mr. Kingsnorth Reeve said it would appear that the sheep contracted the disease through "dipping," yet he had always understood the dip contained sufficient disinfectant to stop anything of the kind.

Mr. Clifford (the local veterinary inspector) said the sheep were never thoroughly immersed, and there was the excretion. He believed the disease was first contracted by the sheep, the period of incubation in them being short. It was quite possible that the infection had been brought over by the foreign dealers. Foot-and-mouth disease was rampant on the Continent; it was very bad in France.—*The Times*.

Food and Feeding Habits of Fish.

The Halibut is a valuable and justly esteemed food fish. It is one of the largest of our fishes; a recent arrival at Billingsgate weighed over 700lb. It is easily the largest of the flat fishes, its nearest rival being the turbot. An interesting point of difference between these two fishes is that the turbot has its eyes on the right side of its head, the halibut on the left. Most of the common flat fishes, such as the plaice, flounder, and brill, resemble the turbot in this respect. The flat shape and peculiar situation of the eyes in those fishes is in correlation with their habits. They live at the bottom of the sea, and are for the most part "ground feeders." Their food, nevertheless, is extremely varied, a matter which has received much attention from the fishery authorities.

In the last annual report of the Fishery Board for Scotland, an interesting account of the food of the halibut is given by Dr. Scott. More than a thousand fish were examined, and the majority were found to have been feeding on other fishes. The haddock and whiting seem to be the favourite food of the halibut, but crabs and lobsters of various kinds are also frequently eaten. Worms and shellfish are disdained, but cuttlefish, which make a fair mouthful, find considerable favour. Other recent investigations of the same nature have been undertaken by Johnstone in the Irish Sea, and on a very large scale by Todd from Lowestoft. Johnstone devoted most attention to the plaice, and found that its food consisted, to a preponderating extent, of shellfish, and in particular the razor-shell (*Solen*). Todd found the same thing on the East Coast, but he showed further that the younger fish lived chiefly on crustaceans and worms, and that it was only as they grew older that they took to shellfish. Another interesting point he made out was that plaice practically stop feeding in November, and do not resume to any extent till March. He also found that the turbot feeds almost exclusively on fishes. These observations are more than matters of curiosity—they throw light on the habits of fishes, the trade in which is a source of considerable revenue.—*B. M. J.*

The Dublin Horse Show.

The forty-fourth annual horse show of the Royal Dublin Society is announced to take place at Ballsbridge on Tuesday, the 22nd August and three following days. Valuable money prizes, cups, etc., are offered for thoroughbred stallions, brood mares, and yearlings, hunters, riding cobs and ponies, and harness horses. Two special jumping competitions over the course are provided—one for British military officers quartered in Ireland, and the other for naval and military officers of any nationality. The entries close (single fees) on the 20th July, and (double fees) on the 27th July. For list of prizes and other particulars apply to the Agricultural Superintendent, Leinster House, Dublin.

REVIEW.

MEAT AND FOOD INSPECTORS' EXAMINATIONS. MODEL ANSWERS TO QUESTIONS SET BY THE ROYAL SANITARY INSTITUTE AND OTHER EXAMINING BODIES. Compiled by G. T. BILLING, Meat Inspector, Metropolitan Borough of Finsbury, and A. H. WALKER, Sanitary Inspector, Metropolitan Borough of St. Pancras. Pp. ix. + 156. Price, 3/6 net. (The Sanitary Publishing Co., Ltd., 5 Fetter Lane, E.C.)

The contents of this small work are fairly indicated by its title. It is chiefly intended for the use of candidates for the Meat and Food Inspectors' Examinations held by the Royal Sanitary Institute; and the great bulk of its matter consists of model answers to questions—150 in all—which have been actually set in recent examinations, the date of each question being given.

The work is prefaced by short but sufficient accounts of the regulations and the syllabus for the Royal Sanitary Institute's examinations; and the last dozen pages are occupied by a series of short imaginary *viva voce* examinations, which give a good idea of both the theoretical and practical oral requirements of the Sanitary Institute.

All such works as this are inevitably open to one grave objection—that their use is susceptible to abuse. Intended as examination guides, they may easily degenerate into the merest cram-books in the hands of some students. Having said this emphatically, we must also say that the present volume is about as unobjectionable on this score as any book written on such lines could be. So far as it goes it is remarkably accurate—indeed, with the exception of the first sentence of the model answer to Question 18 (page 15) which might be amended so as to give a clearer idea of the nature of tuberculin, we have no fault to find with its teaching. Again, it does not profess to include every point in the very extensive syllabus of the Royal Sanitary Institute—it simply illustrates the scope and depth of the examination in its various departments; and in this direction, if rightly used, it should be a very valuable guide. It will be very useful to even the veterinary candidate, who has studied far beyond the requirements of the Royal Sanitary Institute in many portions of its syllabus. It will be more useful still to the average candidate for the Meat and Food Inspectors' examinations.

W. R. C.

Personal.

MOTTRAM—PRITCHARD.—On the 18th inst., at St. James' Church, Piccadilly, James Cecil, son of the late J. A. Mottram, Esq., to Rhoda, daughter of the late Prof. W. Pritchard.

Mr. JAMES THOMPSON, M.R.C.V.S., Oban, has been appointed Veterinary Inspector for the County of Sutherland. Mr. Thomson is a Lieutenant Veterinary Surgeon to the Lovat Scouts.

Mr. L. W. WYNN LLOYD, of Carnarvon, has been appointed a Local Veterinary Inspector to the Board of Agriculture.

From a recent exchange we learn that a course of lectures and practical demonstrations in meat inspection by Mr. MAX HENRY, M.R.C.V.S., of the Stock Branch, Dept. of Agric., Sydney, was opened at the Sydney Technical College, on May 31st. The course will consist of about sixteen lectures and eight practical demonstrations at the abattoirs.

Major EDWARD COLEMAN, formerly of the Honourable Artillery Company, veterinary surgeon to the City of London Corporation, and a director of the Mitcham and Wimbledon District Gas Light Company, who died on June 9, left estate of the gross value of £123,618, of which the net personalty has been sworn at £110,909. The testator left £1000 to the Victoria Veterinary Benevolent Fund upon trust for investment, to apply the income to general purposes.

At a recent meeting of the Natal Provincial Council Mr. Schofield proposed, and it was carried: That the Council places on record its high appreciation of the work of Mr. H. Watkins-Pitchford, Government Bacteriologist, in determining the life stages and action of ticks in connection with East Coast Fever and the discovery of a laboratory dip for the destruction of tick life and the prevention of East Coast Fever and other diseases in cattle; also that in view of the great need for a continuance of varied bacteriological and other investigation, the work at Maritzburg is of the greatest importance, and care should be taken to prevent any lessening of efficiency.—*South Africa*.

ARMY VETERINARY SERVICE.

Extract from *London Gazette*,

WAR OFFICE, WHITEHALL, July 7.

TERRITORIAL FORCE. UNATTACHED LIST.

Albert Edward Mettam, James Joseph O'Connor, James Ferguson Craig, George Thomas Dunne, and Francis Bernard Hayes to be Lieutenants for service with the Royal Veterinary College of Ireland Contingent, Senior Division, Officers Training Corps. Dated May 18.

July 11.

REGULAR FORCES. ARMY VETERINARY CORPS.

Seconded for service with the Egyptian Army. Dated May 20th:—

Capt. F. A. S. Moore and Lieut. J. J. M. Soutar.

July 18.

ROYAL HORSE GUARDS.

Vet.-Major F. B. Drage to be Vet.-Lieut.-Colonel. Dated July 18.

CORRESPONDENCE.

ANTHRAX IN HORSES.

Sir,

I have read with interest Mr. Carter's case of anthrax in the horse. Having had to deal with many cases of this disease affecting horses, horned stock, and pigs, I thought it might be of interest to briefly refer to the symptoms as shown by the horses.

My last case, which I will call No. 1, occurred on our Corporation Sewage farm. A four-year-old cart gelding, lying out at grass, was discovered in the early morning showing symptoms of acute abdominal pain. He was brought into a loose box and on my arrival at the farm had just died. There were no external swellings of any kind, no discharge from nostrils or rectum, and the carcass was not distended, he only rolled just before death. As I knew the farm was an anthrax infected one, I made a blood smear, and microscopical examination revealed the presence of anthrax bacilli in immense numbers. The horse was seen the previous

night by the farm manager and was apparently well and grazing.

Case No. 2, on the same farm, was three-year-old cart gelding; my attention was called to him about 6.50 in the evening, the carter stating "he seemed a bit dull, and poked his head out." He thought he might be going to fall with strangles. I went back with the man to the farm, and we found the colt dead. He had been grazing with some more colts, and seemed all right in the morning. The only external symptoms was a slight swelling of the face; no discharge from nostrils, mouth, or rectum which we generally find in cattle. A blood smear was taken and anthrax bacilli were present in numbers.

Case No. 3. On another farm (not a sewage farm) a young cart horse showed the following symptoms: head, neck, and throat enormously swollen, sanguinous discharge from nostrils, making a harsh roaring noise in his respiration. He died the same night I saw him. A heifer and some pigs having died from anthrax just previously, it was evident what ailed him. Microscopical examination of blood taken from ear showed anthrax bacilli in large quantities.

I may say all these cases were confirmed by the Board of Agriculture.

I should be glad to hear the experiences of any member having had cases of this disease on *sewage farms*, and if any steps taken have been of service in checking its ravages. During the past 4½ years we have lost upwards of 26 bullocks, and the two cart horses mentioned, all cases being verified, and the majority of the animals have been cremated. We had a cessation of the disease for 14 months, and then lost *Case No. 1* and two bullocks this month. Will anyone who has had experience of the disease abroad, state if they have seen goats affected; I have not heard of a case in this country.—Yours faithfully,

CHAS. WOOD PAGE, F.R.C.V.S.

THE VETERINARY BILL.

Sir,

We have for some very considerable time had before the profession, especially in *The Veterinary Record*, the advantages we, as a profession, are going to derive when this Bill becomes law. On reading through the draught of the altered Bill the only advantage that the struggling practitioner will derive, as far as I can see, is the "pleasure" of paying a guinea a year for the doubtful advantage of being a M.R.C.V.S., after what he or his parents have paid for that advantage.

If those who framed the Bill had inserted a clause to prevent the employment of unqualified assistants, that would have been of some advantage to the veterinary profession, not only to the younger members but to the *legitimate* practitioner, as then certain M.R.C.V.S. would not be able to engage unqualified assistants at a wage and under the conditions which no self-respecting M.R.C.V.S. would accept, but it would preclude these same members of the profession from undertaking contracts etc. at a price at which they can do neither credit to the profession or themselves. I believe there is such a thing as "chickens coming home to roost," and I know "those who live in glass houses should not throw stones." If our Council were composed of men who had to obtain their living as general practitioners, they would then know more of the difficulties with which these have to contend, but being in assured positions or in receipt of a pension they know nothing of the "ups and downs" of the "common" practitioner.

ONE WHO KNOWS.

OBJECTORS TO THE BILL.

Sir,

Unless the "Devil" will belie his character and come out of his hiding, I must count him a thoroughly unworthy opponent, and decline to take any further notice of his anonymous libels, which, because they are anonymous, are a disgrace to decent correspondence.—Yours, etc.,

HENRY DYER.

Brompton. July 17.

[We differ from our correspondent in one respect. The mere fact of anonymity can in no way be disgraceful.—Ed.]

PROFESSIONAL ADVERTISING.

Sir,

I have enclosed you a cutting from *The Walthamstow Guardian*, of July 7th. Will you kindly find space in your paper for this.—Yours faithfully,

W. W. SCALES.

Plaistow, July 17.

ANIMALS HOSPITAL, LEYTON.

Mr. E. H. SCOTT, M.R.C.V.S., Lond.,

Formerly Veterinary Surgeon to Carl Hagenbeck and Wombwell and Bostock's menageries, Examiner to the Indian Government and the King of Italy, and Operative and Consulting V.S. to the Animals' Hospital, Knightsbridge, begs respectfully to inform the inhabitants of Leyton and district that he has taken over the business of Veterinary Surgeon at

727 HIGH ROAD, LEYTON.

formerly conducted by the late Mr. Charles Skelton and more recently Mr. Pinson Case.

Dogs left for board during owner's absence from home are under the care of his son, Mr. Eustace Scott.

ON SWINE FEVER.

Sir,

My conclusions as to the cause of this disease are based on the following:—

Swine fever was scheduled in the year 1879. If statistics are right, no progress has been made in its eradication.

The late Mr. Stamford Edgar, Chief Veterinary Adviser to the Kent County Authorities, said every pig harboured the disease and that it would be impossible to stamp it out unless pigs as born were put in a glass case.

In the early eighties the Kent County Authorities insisted upon the Metropolitan Authorities killing out their pedigree herd of some 400 pigs at the M.D. Asylum, and there was a thorough investigation with its usual accompaniment of ink spilling. Being engaged for several days in killing out the herd and opening every one, I saw the disease in every stage. Dr. White's earliest lesions proved to be of the nature of a perforation under the lens. Not of the nature of typhoid were the opinions of Klein, Brown, Axe, Robertson and Williams, who were then investigating swine fever.

An animal with complete strongylosis can infect some 4,000 animals during 24 hours, as per Cobbold. To wit, huck in cattle, sheep, and poultry.

Take a powerful glass directly after killing a pig and you can find the strongyle attached to the early ulcer and follow it up as per Williams' description!

The history of swine fever to a man used to investigating contagious disease will bring the question of strongylosis to the front.

Of the nature of strongylosis, phagocytosis, etc. I must plead grave ignorance, in fact as an old practitioner once expressed to me, "We know nothing until we are practically worn out as country practitioners."—Yours etc.,

GEO. UPTON.

THE "HOLIDAY" DIFFICULTY.

Sir,

There must be many practitioners who, like myself, find the expense and worry or uncertainty of locums debarring them from a change, now why cannot those who find themselves in this predicament exchange practices? The average country practice at this time of the year can be worked with little trouble, leaving ample time to enjoy the change.

Might I suggest a weekly column in your journal for those who are anxious to avail themselves of this arrangement. Speaking for myself I am open to exchange with any country practitioners, and as I reside in the Midlands I should prefer for the sake of the change either Ireland or Scotland.—Yours truly,

July 5th.

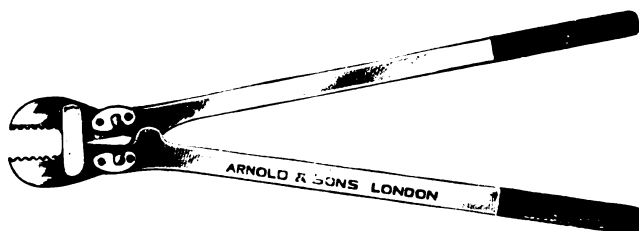

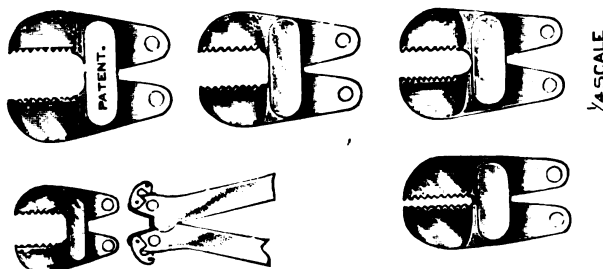

MIDLAND.

Practices for Disposal

DEATH VACANCY. An opportunity of securing an old established country practice has occurred on account of death of principal. Situate in Eastern Counties. Represented as returning considerably over £400 p.a. Good contracts returning £160. Good house and premises at £45 p.a. Hunting in immediate vicinity. Further particulars and introduction only to would-be bona-fide purchasers.

15 MILES OF LONDON. A good-class mixed practice represented as returning about £650 p.a. is for immediate disposal. Capable of considerable increase. Nice and convenient house consisting of 10 rooms. Good stabling, coach-house and dog kennels. Strictest investigation courted. Good introduction will be given. Satisfactory reason for relinquishing. Further particulars on application.

DEATH VACANCY. An old established practice in a London Suburb is for immediate disposal, represented as returning £150. This amount, it is stated, can be easily increased by an energetic Practitioner. Price asked is £100 to include drugs, instruments, kennels etc. Inclusive rental of premises £1 2s. 6d. Further particulars and introduction on application

SALOP.—We have just had placed in our hands for disposal a well-established Practice represented as returning last year £375. County Council appointments. Good reasons for selling. To an immediate purchaser Vendor will accept an offer of about £250 to include Surgery fittings, drugs, instruments, etc.

The Record is posted to Subscribers on Friday, usually in time for the 5 p.m. collection. The normal issue consists of 16 pages of literary matter but this is varied to 20 or to 12, as may be required.

PRACTICES FOR DISPOSAL.

SOUTH EAST COAST. Receipts 1910 £415. Good house, kennels, etc. Very well fitted surgery. Rent £40. Premium £450 and valuation.

SOUTH OF ENGLAND. In present hands 24 years. Receipts last two years average £835 including appointments £70. Convenient house, rent £21, larger house available if preferred. The practice has been worked principally by an assistant who would remain if desired. Premium only £800.

SOUTH COAST PARTNER WANTED. Receipts about £800 per ann. Good house available at moderate rent.

YORKS. Practice principally horse and cattle. Books 1910 show £575. Large convenient house with model stables for seven horses. Well fitted surgery. Rent £75. Practice very compact and easily worked. Premium £375.

NEAR LONDON. Present hands 9 years. Small house rent £30, the practice is principally canine and is easily worked. The returns are stated to be about £400 per ann. Premium one year's purchase.

KENT. High-class mixed practice, returning about £650 per ann. Good premises to be let on lease would be sold. Premium £600.

YORKS. Premium £250. Receipts 1910, £330. Rent £40. Stables and yard almost clear rent. Good agricultural and breeding district. Present hands nearly 20 years. Good house.

LONDON. Thoroughly sound practice, established over 100 years. Receipts about £1200 p.a. Fine house and thoroughly convenient premises. Rent £90. Practice is principally horse. Receipts increasing. Premium one year's purchase.

SOUTH COAST. Old-established Practice for Sale, returning about £550 per annum. Present hands five years. Convenient house, rent moderate. Premium £500.

LONDON. Present hands 30 years. Vendor retiring. Mixed practice. Rent £75. Receipts average £1078. Premium one year's purchase. Strongly recommended.

SEASIDE. Partner Wanted in old-established Practice capable of great increase. Receipts approximate £700. Working expenses low. Good house, rent £60. Premium for half-share £350.

SOUTH OF ENGLAND. Receipts average £650. In present hands 13 years. Usual fees. Good house, three stalled stable, four loose boxes, kennels, cat house, etc. Rent £85. Delightful residential locality. Vendor is well-known to us. Premium £750.

SCOTLAND. General mixed practice returning nearly £700 per annum. Contracts and appointments produce £250 per annum. Practically no night work. Established 30 years, 17 years in present hands. Good house, property of vendor. Rent £60. Premium one year's purchase.

Professional Advertisements.

These will be received up to Thursday morning.
Five lines or under 2/6 (exclusive of heading): for two insertions 4/-; for three 5/-; after three 1/- each.
Each line above five—first insertion 6d; after first 3d.
Average—seven words in a line.

These Advertisements will not be inserted unless prepaid, and if replies are to be received at this office an extra sixpence must be included.

Wanted

LOCUM (Cyclist) for a fortnight, unqualified man not objected to. Reply stating terms and references to 1507 V.R., 20 Fulham Road, London, S.W.

Locum Tenens

SON and Brother of V.S. is open to engagement as locum until October, when returning to college. Highest references from well known practitioners. Address, 2507 V.R., 20 Fulham Road, London, S.W.

Wanted

RECENTLY qualified assistant, with or without intention of taking up a share in good mixed practice, chiefly equine and canine. Please state qualifications and give recent testimonials, etc. Horseman desirable. Live out. Address, 3507 V.R., 20 Fulham Rd., London, S.W.

Assistant Wanted

PRACTICAL assistant for town and country practice. State age, height, references and salary required, live out. Address, 4507 V.R., 20 Fulham Rd., London, S.W.

As Assistant or Manager

M.R.C.V.S., 28, experienced, desires position as above in good-class horse and dog practice. Would not object to going abroad. Excellent references. Address, 6507 V.R., 20 Fulham Road, London, S.W.

As Assistant

CLASS C student will give services for keep and expenses. Served pupillage in a large mixed practice. Ride and drive. Address, J. A. Ward, 7 Crawford Avenue, Bolton, Lancs.

Class D Student

RECENTLY rejected, desires position as assistant, services in exchange for board, or as locum in a busy country practice. Address, D.M., Veterinary Coll. London, N.W.

For Sale

VERY light road cart, nearly new, by Messrs. Mills, London. Address, H. Yeomans, M.R.C.V.S., Kidderminster.

Wanted

PARTNER with view to succession, in good mixed practice, returning about £500, room for considerable increase, half share £250 clear. Address, 5073 V.R., 20 Fulham Road, London, S.W.

Mallein and Tuberculin

MEMBERS of the Profession may obtain Mallein and Tuberculin on application to the Principal, Royal Veterinary College, Camden Town N.W., on the following terms: in bottles, 6d. per dose. Minimum quantity supplied, two doses. In hermetically sealed tubes, containing one dose each (specially suitable for use abroad) 1s. per dose.

G. H. PICKWELL, M.R.C.V.S.

Locum:

73 Victoria Mansions,
South Lambeth Road, S.W.

HUGH R. SINGLETON, M.R.C.V.S.

LOCUM TENENS.

Disengaged August 18th,
44 St. Michaels Road,
Bedford.

For Disposal

IMMEDIATELY, sound country practice, doing between £400 and £500. Must be sold, sacrifice. Bell and Park, Queen Street, Exeter.

Assistant Wanted

FOR London cart horse practice, recently qualified preferred; steady, sign bond. Apply, with full particulars, live out. Address, 5507 V.R., 20 Fulham Road, London, S.W.

Improver Wanted

FOR London cart horse practice, steady, board and remuneration for services. Apply, with full particulars. Address, 7507 V.R., 20 Fulham Rd, London, S.W.

Wanted

IN a mixed practice, Home counties, assistant for about a month. Class D student not objected to if practical. Write &c., experience, salary, references, and when disengaged to 9507 V.R., 20 Fulham Road, S.W.

For Disposal

M.R.C.V.S., going abroad immediately to take up appointment, wishes to dispose of country practice, small but capable of great extension. Unopposed, good agricultural district, capital hunting, 3 packs. Small price for quick sale. Address, 5072 V.R., 20 Fulham Road, London, S.W.

Locum Wanted

LOCUM, used to country practice, and a good horse-man, wanted on August 8th, for about a fortnight. Apply, with references and terms to S. A. Winkup, M.R.C.V.S., Montgomery, North Wales.

For Sale

HUMBER Motor Cycle, listed £47. Warranted smart machine in perfect running order suit busy young practitioner. Exchange considered—books or instruments, no rubbish, cash £15 or offer. Address, 8507 V.R. 20 Fulham Road, London, S.W.

All communications respecting advertisements should be addressed to

H. & W. BROWN, 20 Fulham Road, London, S.W.

Tracheotomy Tubes

MISS JONES, successor to F. B. Jones, M.R.C.V.S., still continues to supply the Special Tracheotomy Tubes patented by her late father. Special terms to Veterinary Surgeons. Address, 86 Kimberley Road, Leicester.

To Veterinary Surgeons

LOCUM, assistant, branch manager, veterinary surgeon desires permanency, sporting, hunting, country practice. Experienced, reliable, practical, hard worker, castrate standing, good obstetrician, 34, single. Excellent references, interview. Address, 5074 V.R., 20 Fulham Road, London, S.W.

Wanted

QUALIFIED assistant for a large mixed practice, please state age, height, weight, and salary asked, also give references. Address, 5075 V.R., 20 Fulham Road, London, S.W.

As Locum Tenens

REQUIRED by thoroughly practical M.R.C.V.S., town or country. Address, 52 Brownswood Road, Finsbury Park.

As Assistant

PRACTICAL class C man requires situation in busy mixed or country practice. 1st class with microscope. Would stay through winter. Address, 5071 V.R., Fulham Road, London, S.W.

Wanted

PRACTICE returning about £700 a year: must bear strict investigation, and good introduction given. Advertiser has ample capital. Address, 4076 V.R., 20 Fulham Road, London, S.W.

To Veterinary Surgeons

WANTED to act as manager of country practice, with view to succession. Good references. Address, 4075 V.R., 20 Fulham Road, Loddon, S.W.

For Disposal

DEATH vacancy, Staffordshire, horse and canine practice, situated in centre of town, receipts £250 per ann., could be greatly increased. Good house, and kennels; working expenses small. Good introduction. Reasonable to immediate purchaser. Address, 3075 V.R., 20 Fulham Road, London, S.W.

Assistant Wanted

IN London Suburban practice, with knowledge of canine work. Live out. State age, salary, experience, and references. Address, 3078 V.R., 20 Fulham Road, London, S.W.

CHEAP BOTTLES.

A large quantity of named medical bottles (these have various chemists' names on and washed ready for use)
2oz., 3oz., 4oz., 6oz. and 8oz. at 5/6 a gross.
10oz., 12oz., and 16oz. at 7/- a gross.
Cash with order. Carriage paid on £3 orders within 70 miles, and on £5 orders any distance.
Other bottles and jars quoted for.

F. NEEDHAM,

Beaconsfield Road, Acton Lane,
Chiswick, London, W.

The Journal of The Board of Agriculture

ISSUED on the 15th of each month. Twelve months 4/-, three months 1/-, or single copies 4d., direct from the Board of Agriculture and Fisheries, 4 Whitehall Place, London, S.W., or through any bookseller.

For Immediate Disposal

WORKS, North Riding. Wanted, reasonable offer. Receipts over £300, good house to go with practice. Rent £12. Good agricultural and breeding district. Present owner 27 years; no opposition; C.C. appointment; introduction given. Address, 5307 V.R., 20 Fulham Road, London, S.W.

For Disposal

MIXED practice in West hunting country, old established; premium £20. Address, 7307 V.R., 20 Fulham Road, London, S.W.

Partnership

WANTED, junior partner (succession in a year or two) in horse and cattle practice returning about £600 with room for considerable increase. Half share £250 and valuation. Address, 8307 V.R., 20 Fulham Road, London, S.W.

Assistant Wanted

FOR town practice. State age, references and salary required. To live out. Sign usual bond. Address, 1107 V.R., 20 Fulham Road, London, S.W.

Locum Tenens

M.R.C.V.S., thoroughly used to country practice and holding testimonials as to ability and general character from many practitioners, is always open to engagement when not actually filling a post. Permanent Address, "Locum," 59 Gascony Avenue, London, N.W.

For Disposal

GENUINE old established town practice and shoeing business in Lancashire. Good premises, with every convenience for doing a large and profitable trade, carried on successfully for many years by owner, who is retiring. Address, 4042 V.R., 20 Fulham Road, S.W.

The Glasgow Veterinary College,

INCORPORATED.

Principal: JAMES MCCALL, F.R.C.V.S.
Session, 1911-1912.

This College is under the management of a representative Board of Governors and is recognised as a Central Institution under the Education (Scotland) Act, 1908. A complete course of instruction is given in the subjects of examination for the Diploma of the Royal College of Veterinary Surgeons, and the field for clinical observation is unsurpassed. The equipment of the College is being extended and modernised. Students are eligible for bursaries granted by Secondary Education Committees of the Counties and certain Burghs of Scotland.

The Matriculation Examination conducted by the Educational Institute of Scotland for intending Students will be held on 6th, 7th, and 8th July, and 7th, 8th, and 9th September.

Next Session commences on Wednesday, 27th Sep. 1911. Further particulars may be had on application to the Principal, or Alexander Russell, 54 West Nile Street, Glasgow, Secretary.

See also page VII.

Royal Veterinary College, London.

(Founded 1791.)

Principal and Dean : Professor **SIR JOHN M'FADYEAN, M.R.C.V.S., M.B., B.Sc.**

Membership Diploma of the Royal College of Veterinary Surgeons :

Complete Courses of Instruction are conducted in all the Subjects of the Examinations for this Diploma. The facilities etc., afforded for the Practical Training of Students are unrivalled.

Bachelor of Science Degree, University of London.

The Professors of Chemistry, Biology, Anatomy, Physiology, Hygiene, and Pathology, are Recognised Teachers of the University, and conduct in their respective subjects courses which qualify for the Science Degree (B.Sc.) which may be taken concurrently with the above Diploma.

POST GRADUATE COURSES.

These Courses in Veterinary Pathology and Bacteriology are conducted under the supervision of the Principal and are specially adapted to the requirements of officers of the Army Veterinary Department, Colonial Veterinary Surgeons, Veterinary Inspectors under the Contagious Diseases of Animals Acts and Candidates for the Fellowship Diploma of the Royal College of Veterinary Surgeons.

The number of places for these Courses is limited and early application must therefore be made to prevent disappointment. The next Course will begin on Monday, October 9th, and terminate on Friday, December 1st.

The College Calendar, containing full particulars, will be forwarded on application to

The Secretary,
Royal Veterinary College, Camden Town, N.W.

Saloform Pessaries.

The New Uterine Antiseptic

Highly recommended by many eminent
Veterinary Surgeons.

PRICES: Ordinary Strength, White.

4/6 per doz. 48/- per gross.

Extra Strong, Yellow.

6/6 per doz. 72/- per gross.

Sole Proprietors—

HARKNESS, BEAUMONT & CO.,

Wholesale Chemists,

EDINBURGH.

Veterinary Surgeons have for long keenly felt the want of something which could be used with good results as a Uterine Antiseptic and which at the same time could be quickly and easily administered. After many trials, and with the kind co-operation of some able Veterinary Surgeons of great experience in parturition cases, we have succeeded in producing

a Pessary made with a non-oily base which does its work efficiently and at the same time is non-irritant—in fact, soothing in its effect. They are of great use in parturition in cows or mares; and if administered immediately after parturition they will keep the Uterus clean and healthy, and prevent the after-birth becoming foul.

Veterinary Surgeons in various parts have highly recommended them, and there is an increasing demand for both kinds.

Customers are requested when ordering to state which kind they prefer.

A RECENT UNSOLICITED TESTIMONIAL.

AINSWORTH WILSON, ESQ., F.R.C.V.S.,
writes:—

"I have used the Saloform Pessaries supplied by Messrs. Harkness, Beaumont & Co., of Edinburgh, with good results in various diseases of the genital organs, both in mares and cows, more especially after parturition. They are particularly useful in retention of the afterbirth, with septic complications. It is often impossible to attend more than once a day to irrigate the uterus; in such cases it is good practice to leave one or two of the "extra strong" pessaries *in situ*. I have found them an excellent substitute for Iodoform and other well known non-irritating antiseptics. I feel justified in recommending them to the profession.

Witham, Essex.

THE VETERINARY RECORD

A Weekly Journal for the Profession.

EDITED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1203.

JULY 29, 1911.

VOL. XXIV.

THE NATIONAL MEETING.

The annual meeting opened on Tuesday morning, at the Guildhall, Carnarvon, with only a moderate attendance: this may be accounted for by the locality—on a coast line of railway; possibly also by doubts as to the weather, though that could scarcely be pleasanter—not too much sunshine, fresh breeze, and a very occasional passing shower.

The proceedings followed the usual course. The Association accepted the invitation of the Lancashire Society to visit their county in 1912—the jubilee year of their Society's existence: and as a not unexpected sequence, Mr. W. Woods, of Wigan, was unanimously and enthusiastically elected President for the ensuing year.

The report of the Committee on the Union of the Societies, which embodied some verbal alterations, making the revised rules a little more definite on a few points, was received and adopted, and Dr. Bradley, Mr. Gofton, and the Committee were deservedly thanked for their work. It is well over two years since this scheme was first brought forward, and now, by its completion the profession is provided with a means of concerted action, a powerful engine of defence if used, and used judiciously. The Committee was reappointed to complete details and bring the matter into working order.

Dr. Bradley's paper on "Veterinary Education" was not discussed. The discussion turned on the need for such an improvement, and the scheme itself was accepted almost *in toto*. Mr. Brittlebank, in opening, spoke strongly on the necessity for more practical teaching in meat inspection and in other matters connected with duties of veterinary surgeons employed by municipal bodies. Mr. Woods pointed out the apathetic manner in which this question of municipal employment had been put aside in previous years, and both he and Prof. Woodruff urged strongly that action should be taken at once; and the latter also expressed his conviction that the Royal College of Veterinary Surgeons might institute the proposed new Fellowship Diploma in Public Health without fear of loss—that the additional cost in examining would be met by the increase of candidates for the Degree.

The afternoon was devoted to the discussion on Dr. Annett's paper on the "Sclerostomes," opened by Mr. A. W. Noel Pillers and Dr. Leiper, and as might be expected, in the hands of such men, proved both interesting and instructive.

The Annual Banquet was held in the evening at The Sportsman Hotel, when between 60 and 70 sat down; the guests included Lady Roberts (Lady Mayoress), the Deputy Mayor and Mayoress, Dr. Parry (M.O.H.), Dr. Parry-Edwards and others. The dinner was good and well served: that most genial of chairmen, Mr. T. S. Price, was in his best form: the speeches were none of them long: the music—vocal and harp—were well selected and capitably rendered, and the function was freely acknowledged to have been a decided success.

BIER'S TREATMENT BY ELASTIC COMPRESSION.

Recently we have had some additions to the still scanty clinical records of the results obtained from Bier's compression treatment in this country. At the last meeting of the Yorkshire V.M.S., which we reported on the 8th inst., Mr. Sampson gave details of some successful cases, and Messrs. Clarkson and Pillers gave equally favourable reports from their own experience. Mr. Sampson commenced by remarking that the treatment was less widely employed by veterinary surgeons than it deserves to be, judging from the results obtained; and the general trend of the discussion seemed fully to corroborate this opinion.

Nevertheless, there is no doubt that the method is gaining ground amongst us, though perhaps rather slowly. The Yorkshire discussion revealed plenty of interest in it, and probably a similar discussion by any Society of equal size would show much the same state of affairs—some members already having experience of the treatment, others inclined to try it. There may or may not yet be a clinician in this country whose experience of the method is sufficiently extensive to encourage him to present a comprehensive paper upon it to an Association. If there is, such a paper should now be especially valuable.

The existing evidence points to the conclusion that elastic compression is a valuable addition to veterinary surgery. Some of its best veterinary results, moreover, have been gained in conditions which are not only common, but also often very unsatisfactory under older methods of treatment. Undoubtedly it has its limitations; and these should be better understood. Possibly, also, it may be found that its technique is capable of further improvement for veterinary patients; and certainly its application will always demand care. The duration of the periods of compression and the intervals between them, for instance, are not yet accurately estimated; and in this respect English clinicians hitherto seem sensibly to have kept well upon the

safe side. Some foreign ones, however, have considerably exceeded the English periods, and apparently without ill results.

Much experience and careful observation will be necessary before we can pronounce finally upon the value of this treatment. But, considering the favourable present reports of its results, and its wide applicability in veterinary practice, it deserves most careful trial from the clinician.

ABSTRACTS FROM FOREIGN JOURNALS.

THE TOTAL PROLAPSE OF THE RECTUM IN PARTURIENT MARES.

Jos. Hamoir, of Bois-Borsu, publishes a long article upon this condition, applying his remarks solely to its occurrence in mares. This accident, as is well known to all practitioners concerned with equine obstetrics, is very frequent when the expulsive efforts of the parturient mare are violent and excessive. It is not, however, confined to cases in which the parturient pains are violent and protracted, but may also occur in the course of a normal or nearly normal labour; and it is much more likely to occur when the rectum is filled to repletion with fæces. Hamoir, indeed, regards the last-named factor as a very important one; believing that its presence is essential, or at least very favourable, to prolapse.

Again, when parturition is protracted from any cause whatever, the abdominal pressure and the uterine pressure acting concurrently upon the very movable rectum may induce rectal prolapse. The condition is characterised by the appearance externally of from one foot to five feet of gut, which of course really corresponds to a total displacement of exactly double this length.

If the organ has remained a long time outside the body, so that it is œdematous, cold, purple, and more or less seriously traumatised, reduction is useless, as death is certain to follow. If, however, prolapsus appears in the presence of competent attendants, reduction is not difficult; and if too large a quantity of gut has not been extended, a favourable result may follow. It is necessary, however, to remember the secondary effects of prolapse of the rectum, which can be understood from a consideration of the anatomical relations of the organ.

A small prolapsus may leave the peri-rectal *cul-de-sac* of the peritoneum and the meso-rectum undamaged. But if the prolapsus involves two feet or more of intestine the peri-rectal peritoneum, the meso-rectum, and perhaps even the meso of the floating colon, are ruptured to a greater or less extent, constituting a fatal complication. The prolapsus may be reduced, but the portion of intestine which has been prolapsed is deprived of the vessels and nerves which previously entered its small curva-

ture between the now ruptured peritoneal envelopes. Paralysis and anæmia of the muscular coats of the intestine follows, causing gangrene in the gut, peritonitis, and speedy death.

The diagnosis of these secondary lesions is not difficult. If the visible portion of prolapsed intestine has attained a length of one foot, these complications are to be apprehended. If, when reduction has been quick and easy, constipation follows; and if exploration of the rectum reveals an open anus, a dilated and flaccid rectum, and a rectal mucous membrane dry and devoid of mucous, rupture of a portion of mesentery may confidently be diagnosed. The expulsion of gas and the immediate rejection of clysters which occur are due to the action of abdominal pressure, not to contraction of the muscular tunic of the intestine.

The condition of the animal rapidly alters for the worse. Fever appears in a few hours, and loss of appetite, constipation, straining, and dull colicky pains persist till death, which takes place in four or five days from septicæmia and peritonitis.

The progress is extremely grave. Hamoir has collected statistics of 15 cases (3 being his own) of which only one recovered, representing a mortality of more than 92%.

Treatment. Manual evacuation of the rectum, emollient clysters, and purgatives may prolong the life of the patient, but does not save it. The sole rational therapeutic measure consists in the resection of the portion of intestine which has been deprived of its vascular and nervous supply. The prolapsus should be reproduced, which is not difficult of accomplishment, and the whole of the prolapsed portion should be resected a few centimetres (1 c.m. = 4/10ths inch) from the anus. The two concentric ends of the rectum are then sutured according to surgical principles—Hamoir here refers the reader to the technique advised in Degive's *Precis de Médecine Opératoire*.

Hamoir has practised resection of the prolapse (following Lanzillotti's technique) in one only of his own three cases. In that case he failed; but undoubtedly the operation was attempted too late. The prolapse had been immediately reduced, but constipation had been evident from the moment of reduction, while the temperature rose. Hamoir did not operate until the third day, when peritonitis was already evident; and the mare only survived the operation twenty-four hours.

When the prolapse is an extensive one, Hamoir advises immediate resection, without wasting time over reduction. The latter is easy of accomplishment, but its success will be ephemeral in extensive cases.

As a precautionary measure against prolapse, Hamoir advises (basing his advice upon his above stated belief of the importance of fecal accumulations in the rectum as a causal factor) that the mare should receive one or several evacuating clysters at the commencement of labour.

These two therapeutic indications are the main conclusions of his paper.—(*Annales de Méd. Vét.*)

Royal College of Veterinary Surgeons.

EXAMINATIONS IN LONDON.

At the meeting of the Board of Examiners held in London on July 14th for the Written, and on July 18th, 19th, 20th for the Oral and Practical Examinations, the following gentlemen passed their Final Examination:

Mr. R. B. Cockburn	Mr. F. F. Horton
T. J. Davis	F. C. Minnett
J. T. Edwards *	W. A. Pool
J. A. G. Gosling	S. C. Rowbotham
G. V. Golding	S. Smith
F. E. Heath	W. P. Stokes
H. E. Hornby	G. F. Steevenson *

EXAMINATIONS IN LIVERPOOL.

At the meeting of the Board of Examiners held at St. George's Hall on July 14th for the Written, and on July 19th, 20th, and 21st for the Practical Examinations, which were held at the University of Liverpool, the following gentlemen passed their Final Examination and were admitted Members of the Royal College of Veterinary Surgeons:

Mr. P. McGregor	Mr. D. R. Hoddinott
F. J. Richmond	S. K. Jones *
G. G. Howard	T. Craig

The following passed their Third Examination:—

Mr. W. Andrew	Mr. J. W. Procter
H. Sumner *	R. Isherwood *
A. L. Pollard	

The following passed their Second Examination:

Mr. A. B. Gately	Mr. C. Wadsworth
J. Blackburn *	R. Dawbney *
C. W. Elan *	J. A. Ward *

The following passed their First Examination:

Mr. R. P. Holmes †	Mr. E. N. Kinsey
G. Lloyd *	

Marked thus * passed with Second Class Honours.

CHAS. BLACKHURST, M.R.C.V.S., Local Sec.

CENTRAL VETERINARY SOCIETY.

The last meeting of the present Session was held at the Royal College of Veterinary Surgeons, Red Lion Square, on Thursday, July 6. Mr. W. S. Mulvey, President, was in the chair, and the following Fellows signed the attendance book: Messrs. A. L. Butters, J. Willett, A. Crabb, P. W. D. Smith, N. Almond, B. Gorton, F. G. Samson, Prof. H. A. Woodruff, W. Perryman, G. H. Livesey, F. H. Sanderson, J. A. Gosling, Prof. G. H. Wooldrige, W. L. Harrison, H. D. Jones, Ainsworth Wilson, J. W. McIntosh, William Hunting, and Hugh A. MacCormack, Hon. Sec.; and as visitors, Messrs. J. S. Lloyd and R. Stokoe.

On the motion of Mr. Butters, seconded by Mr. Samson, the minutes of the last meeting were taken as read and confirmed.

CORRESPONDENCE.

Letters regretting inability to be present were received from Messrs. F. Hobday, J. T. Angwin, R. F. Foreman, E. L. Stroud, and C. Roberts.

A letter was read from the Congress of the Royal Institute of Public Health, asking for delegates to be sent to the meeting in Dublin, on August 15 to 21.

On the proposition of Prof. Woodruff, seconded by Mr. Perryman, Mr. John J. Kelly was asked to represent the Society at the Congress.

ELECTION AND NOMINATION OF FELLOWS.

Mr. G. W. LUCKING, M.R.C.V.S., Chelmsford, Essex, was unanimously elected a Fellow.

Mr. R. STOKOE, M.R.C.V.S., Chelmsford, Essex, was nominated for Fellowship, and will come up for election at the next meeting.

SPECIMENS.

Mr. SAMSON exhibited a portion of the intestine of a small terrier dog belonging to himself which he had had under observation for some time. The animal showed symptoms of unthriftiness, and somewhat arched his back, and at first it was thought to be rheumatism. Any aperient medicine given to him was vomited up on each occasion. The appetite became worse and worse, and the dog thinner, and he suddenly died. On post-mortem, about a foot from the stomach he found a sort of supernumerary growth of a portion of the intestine; very little nutriment could get by the growth, and that only in a liquid form. About 18 months before, the dog had been run over by a motor car, and laid up for some little time, and that was thought to be the origin of the condition.

Mr. JONES showed two fractured pedal bones, and one fractured navicular bone from a horse which had been admitted to the infirmary. There was a good deal of swelling round the coronet, and on the horse being destroyed it was found that the pyramidal process had gone off one pedal bone, the articular surface being fractured in the other.

Mr. PERRYMAN showed an interesting case of fracture of the two first ribs in a mare six years of age. On the previous evening she was said to come in looking perfectly sound. In the morning she had a good deal of pain and lameness on the near fore leg, and he diagnosed it as a case of fracture of the first rib. She was placed in slings but made no progress, and there was no improvement even when she wore a big shoe with support for the knee. He did not suspect fracture on the opposite side, and she never gave any indication of fracture there. It was the second case he had had in twelve months where both first ribs had been broken. In the other case the animal comported herself in exactly the same way, showing lameness on one side with fracture some two inches beyond the articulation. It had occurred to him whether it was not possible that fracture of the first rib might occur without dropping of the elbow. In the present case both fractures appeared to have occurred about the same time. He had noticed in cases of fracture of the ribs that the animal could generally walk for the first two or three days, when dropping of the elbow took place.

Professor WOODRUFF exhibited several specimens, two of them being livers of pigs. The first case was a liver containing large numbers of the *Ascaris suis*. Apparently the parasites had worked their way up the bile duct into the liver, and there was about a couple of hundred of them actually in the organ. The pig died suddenly, and the case was reported as a possible case of swine fever. The inspector making the post-mortem found the abdomen containing blood and a ruptured liver, the cause of the rupture being obviously the irritation due to the presence of the ascarides in the bile ducts.

The second specimen was of a somewhat similar nature, showing the migration of embryo tapeworms in tremendous numbers through the liver. On post-mortem the veterinary inspector found the abdomen full of blood with "something very like a rice pudding" lying on the liver, and the liver itself was ruptured and full of small cysts, not the cystic stage of the tapeworm but minute cysts something less than a pin's head, many of them containing blood. He took the parasite to be the *Tenia marginata* of the dog. The eggs had evidently been ingested by the pig in large numbers, and the embryos had migrated through the liver, and had so softened the organ that it ruptured and the pig died of internal hæmorrhage. A similar occurrence had been described in connection with lambs that had been experimentally fed with the *Tenia cœnurus* of the dog. The immense number of embryos that came through the liver at one time produced this condition of acute hepatitis, softening of the organ, rupture, and death.

The third specimen exhibited by Professor Woodruff was what was called "worm nodules" in beef. There had been a good many terrifying descriptions of what might happen by reason of the worm nodules in beef from Queensland. Recently investigations had been made at the request of the L.G.B., and the cause was found to be a parasite allied to the filaria called *Onchocerca Gibsoni*. Affected beef had been coming in large quantity into the London markets, and quarters of beef infected badly with it were being seized, but there was no danger of infection of the human subject by the parasite.

A further specimen exhibited by Prof. Woodruff was that of small concretions in cooked ham. The ham was sent to him on the supposition that the concretions were parasitic in origin. They were something like measly pork which had become calcified and dried up. He did not, however, think that was the case, as they were in the fat as well as in the muscle, and on dissecting a large number of them out it was possible to dissolve them in strong ammonia. The solution was filtered and then boiled to get rid of the ammonia gas, and then nearly evaporated to dryness, and a drop put on the slide and allowed to crystallize out, with the result that a large number of crystals of tyrosin was obtained. The concretions only occurred in pickled meat, hams, bacon, and cured meats, the small chalky-like bodies being concretions of impure tyrosin. They did no harm whatever to human beings on consumption.

Mr. LIVESEY said that during the last ten or twelve years he had had several cases of a peculiar skin disease in the dog, which he had not seen described in books and to which he could not give a name. In four out of five cases it had occurred in white-haired dogs, and had occurred as an acute dermatitis localised in several patches, varying from the size of a threepenny piece to a five shilling piece. It began with shedding of the hair and acute irritation, and in a day or two, after a certain amount of oozing of serum, a scab was formed, somewhat like a localised follicular mange, with one or two openings in it. He had not been able to find the parasites at that stage commonly found in follicular mange. After a fortnight or three weeks the condition of the patches altered, the skin became very much thickened and bluish in colour, and had lesions looking like small sinuses subcutaneous or within the skin itself, exuding a thin watery pus rather greyish in colour, and, if squeezed, very easily bled. In one dog which had plenty of spare skin he had cut the whole lot out, and the wound healed by first intention. All the cases had been most intractable to treatment by drugs, but with blackwash he had obtained some very fair results. Fomenting and compresses of antiseptics had yielded very moderate success. He thought the best results had been obtained with resin ointment and eucalyptus oil, well rubbed in, with frequent bathing.

Mr. J. WILLETT, referring to the case of double fracture of the first ribs, asked whether there was any evidence of accident. It was easy to see that on one side there had been no displacement and therefore there would be no dropping of the elbow or waste of muscle on that side. It would be interesting to know what forces were at work to cause such an accident.

Mr. W. HUNTING said the fracture on the offside, followed by no waste of muscle, was distinctly above and out of the way of the great plexus, but that on the near side, where there was dropping of the elbow, was directly under the nerve plexus. In nearly all cases it occurred at about the bottom of the upper third of the first rib. He had seen fracture of the lower part of the first rib without the slightest waste of muscle or "dropping of the elbow." He had never made a post-mortem in which both ribs were fractured, but there were two or three accounts in which he had noticed that the horse in some cases was found only on post-mortem to have double fracture, and in one case the horse was killed because he had paralysis of the opposite side. The possibility was that when there were two fractures, the one followed the other, and was due to the fact that the pressure on the two ribs was distributed upon the one that was left sound, and that was weakened to such an extent that a very slight amount of violence was required for fracture.

Prof. WOODRUFF said it was well known with what ease fractures could occur in the horse that had been unnerved; in other words, if nutrition of the bone was upset, fracture was made easier. It would be interesting to know if there was any abnormality such as fragilitas ossium in any case where fractures occurred with great ease, as they sometimes did in cases of radial paralysis or split pastern.

Mr. J. WILLETT asked whether Prof. Woodruff was of opinion that one of the fractures was caused before the other.

Prof. WOODRUFF thought if they occurred at different times the times were very near together, owing to the degree of healing in the bones being similar.

Mr. PERRYMAN said he knew nothing about the internal structure of the bone, but he thought Mr. Willis was the first to point out in England the question of fracture of the first rib, and particularly to remark about the temperament of the animal. It generally occurred in aasty sort of creature, and followed from jumping into the collar. He himself thought it was generally due to a violent muscular contraction when the animal jumped into the collar.

Mr. ALMOND thought Mr. Livesey's case was very interesting, but he had not indicated how he brought about recovery.

Mr. LIVESEY could not say that any treatment had been responsible for recovery. The best result followed the use of resin ointment, and probably was hastened by internal administration of iron and arsenic, combined with good feeding. In the next case he was going to try an injection of staphylococcus or streptococcus vaccine. He mentioned a further case of a cat brought to him suffering very badly from mange, in which he found a large number of the mange parasites on the head and neck, but in equal numbers the ear parasite on the bridge of the nose and round the shoulders. That went some way towards contradicting what was found in text-books.

Mr. HUNTING, referring to the cause of fractured first ribs, remembered a case where a horse and cart went over a sandpit, and when got out the horse had "dropped elbow," but in the majority of cases he had seen there was no fall. In one case in the King's Road, Chelsea, a 'bus horse shied at a piece of paper, hung back in his harness, and then sprang suddenly into his collar; the leg hung powerless immediately. In another case a horse was being driven near Vauxhall, and in pass-

ing under the railway bridge a train came over at the time and the horse shied, stopped suddenly, and sprang into his collar; he also had "dropped elbow" immediately. He could go so far as to say that in nearly every case of "dropped elbow" he had seen it had been in an active, quick-tempered, nervous animal, and there had been no fall.

Prof. WOOLDRIDGE alluded to the case brought forward by Mr. Price at the last meeting, in which the two first ribs were fractured, and said that the explanation that one fracture might have occurred later than the other might apply in that case.

According to the agenda the evening was to be devoted to impromptu discussions, but questions were raised upon which the discussions of the evening turned.

The first question put forward was: "Should a horse with obvious 'dissimilar' coarse hocks, going sound, be passed free from 'spavin,' and if so, how should the certificate of soundness be worded?"

Prof. WOOLDRIDGE thought it was absolutely impossible to give an opinion without examining the horse. It was possible to have a horse with dissimilar hocks perfectly sound, and he had several instances that illustrated the workability and durability of a horse with such condition. In one instance a hunter, 15-3, a very clever horse, priced at £250, was rejected by three veterinary surgeons in succession on account of difference in size of the two hocks. On the fourth occasion he was examined by a Cheshire veterinary surgeon, with whom he (Prof. Wooldridge) happened to be at the time. The veterinary surgeon, a heavy man, got on the horse, and gave him a very severe doing in circles in both directions. The horse was put in the stable and brought out again a little later (20 minutes or so) and he was absolutely free from lameness, and was passed as sound, the certificate simply stating under "recognition marks," "odd hocks." He was able to follow that horse for three seasons, and he was never known to go lame in the leg which had a large hock, though he did get stifle lameness in the other leg in the second season.

Mr. SANDERSON said he had put the question from practical experience. There were horses with hocks thick through the middle, generally at the low end of the tibia, and the astragalus seemed much larger than the other. There was free movement in both legs, and yet one hock was much larger. He mentioned the case of a horse that as yearling developed coarse hocks, one larger than the other, after recovery from influenza, and it was said he was not worth breaking in. He was broken in, however, and he was now 17 years old, and has won five point-to-point races up to and including the present year, and against fresh opposition each time. I don't wish my question to apply particularly to such cases as the latter, though, but to those in general arising without any previous history of disease.

Prof. WOODRUFF said most veterinary surgeons knew of cases where horses with odd hocks had worked and continued to work sound, but he thought the real question was, what was the right attitude to be adopted when examining the horse? It was not only necessary to protect the client, but to protect oneself. Was it wise in the majority of cases to pass such horses without question, or was it not wiser to do as the three veterinary surgeons had done, call the horse an unsound horse, having regard to the fact that in the majority of cases a horse with dissimilar hocks was liable to go lame and to become unsound? He thought that was the right attitude to take up, rather than to act upon a number of examples where horses with odd hocks were sound.

Mr. ALMOND thought it would be very often possible to keep a useful horse from passing into other hands if too rigid a view of one's interests was taken. In his

opinion, the deciding factor in all the cases was the hock action. In a case such as had been put forward, the business of the veterinary surgeon was to examine the animal very carefully, and he thought the mode of examination indicated by Prof. Wooldridge was the proper one. If the horse sustained that test, then it might be sold with the qualification "odd hocks." He should never give a certificate of soundness to a horse of that kind, but give an opinion that the horse in all probability would remain sound.

Prof. WOOLDRIDGE said his first remarks were based entirely upon abstract principles. When a specific case was put forward in which a horse at a known period of his life developed an enlargement of one hock, to his mind that was direct evidence of some diseased condition, and would be an unsoundness.

Mr. HUNTING said when he had a puzzling case he protected himself by pointing out the condition found and then saying, "which I am of opinion will not interfere with his usefulness."

Prof. WOOLDRIDGE asked Mr. Hunting whether he agreed that a horse with such hocks might not have his usefulness interfered with.

Mr. HUNTING said he did, and more than that, he thought an animal could work perfectly sound for years with two big spavins.

Mr. J. WILLETT thought we had no more right to say a horse was sound with odd hocks than to say a horse was sound with odd feet. Personally he had a great objection to write "I certify," much preferring to write a letter to his client.

Prof. WOODRUFF said such a letter if signed was as much an opinion as the stereotyped phrase, "I certify."

A further question asked was: "When a client brings a dog for exportation to such a country as Norway and asks for the usual and necessary certificate of freedom from all contagious and infectious disease, can we honestly give that certificate, and if so how should we word it?"

Mr. LIVESEY said that before a dog could be taken into Norway it had to have a certificate, and it was impossible for any veterinary surgeon to state here that a dog was absolutely free from contagious and infectious disease. He should be inclined to write a letter and say that the dog appeared to him to be healthy in every respect.

The PRESIDENT believed a letter was not accepted by the Port Authorities in Norway, but they would accept a certificate worded "to the best of my belief."

Prof. WOOLDRIDGE thought it was quite sufficient to say, "In my opinion the animal is free from contagious disease." He did not think it was reasonable to expect the veterinary surgeon to diagnose diseases in the incubative stage.

Prof. WOODRUFF said he was asked by a well known barrister to give a certificate that one of his horses was free from contagious diseases and had not been in contact with other animals suffering from contagious diseases within a certain time. But no man could possibly do that, and his reply was that if the horse was sent to the College he would keep him for a few days, subject him to the mallein test, and then write a certificate. He was told that if the horse was sent to one of the ports he could be certified at sight by the veterinary surgeon there. He replied, "You are a barrister, and I should like you to imagine my position in the box if you were the prosecuting counsel, and I had given you the certificate you asked me to give." The horse was taken to the port and he believed was certified on sight and went over to the Continent.

Prof. WOOLDRIDGE said in Ireland they required the certificate to be accompanied by a mallein chart and the temperatures of five observations.

Prof. WOODRUFF raised the question of the use of

the College Crest by practitioners, and referred to the fact that a London practitioner had successfully defended an action brought by the Revenue Department of the London County Council for using the crest. Rightly or wrongly the majority of veterinary surgeons used the crest on their letter paper; there might be two opinions whether it was wise, or judicious, or good form, but it was used by the majority of members. The London member who had defended his action was now threatened with an Appeal, and the question was whether he was to be allowed to fight that Appeal himself or was to have the moral and practical support of the profession. He had no communication from the gentleman in question on the subject, but he was well aware that law was an expensive item, and the proprietors of the two professional journals with which he and Prof. Wooldridge were connected had consented to initiate a fund by a subscription. It was a question of great interest to the profession and one where the professional interest and not the personal should be the deciding factor. Some expression of opinion from the Society would be useful as drawing the attention of the profession to the necessity of providing a fighting fund. The Pharmaceutical Society, when threatened with a similar action some time ago, successfully defended their right. In the interest of the profession he thought Mr. Kirk, the practitioner in question, ought to be helped in defending the Appeal.

Mr. HUNTING said he did not mind giving pecuniary assistance, but he would not give his moral support, as he thought the habit of using the crest was one that might well be dropped.

Mr. J. WILLETT thought it would be better if the Society waited until they were asked to assist.

Mr. SAMSON did not think Mr. Kirk or any other member would appeal to the profession, and the help would come much better from the Society subscribing individually. He believed a member belonging to a club used the club crest, and he saw no reason why a member of the College should not use the College crest.

Mr. ALMOND thought the public spirit of the member referred to was praiseworthy, and although he had never used the crest himself he was prepared to support the defence.

Mr. PERRYMAN was also in favour of giving moral and practical support to Mr. Kirk, not from any personal feeling but from a professional point of view. It would be a support to Mr. Kirk to know that he was backed up by the Society.

Mr. SAMSON moved: "That it be a recommendation from this Society to the Council that a subscription of five guineas be given towards a Defence Fund, if necessary."

Prof. WOOLDRIDGE seconded the motion, which was carried.

Prof. WOODRUFF said it was hoped the Appeal would not be brought, and therefore any promise of support was a promise only at the present time. He pointed out that the British Medical Association had a Defence Fund, and the very fact of the existence of that Fund prevented actions being brought, or if brought being dropped on account of the powerful professional backing of the member threatened. The establishment of this defence fund would not only help to defend this appeal, but if successful would enable similar actions to be defended in any part of the country.

On the proposition of Mr. J. Willett, a vote of thanks was accorded to the gentlemen who had exhibited morbid specimens, and the Session terminated.

HUGH A. MACCORMACK, *Hon. Sec.*

EASTERN COUNTIES VETERINARY MEDICAL SOCIETY.

A meeting was held on Thursday, July 13th, at the Angel Hotel, Bury St. Edmunds, when the chair was taken by the President, Mr. T. G. Heatley, of Woodbridge. Members present were Messrs. W. M. Reeman, Bury St. Edmunds; P. Turner, Ixworth; E. Wright, Yoxford; F. Morton Wallis, Halstead; J. E. Godbolt, Stowmarket; E. A. Hudson, Barrow; Sidney Smith, jun., Lowestoft, hon. sec., and Mr. R. Turner, a visitor.

The following sent apologies for inability to attend: Sir J. M'Fadyean, Prof. F. T. G. Hobday, Prof. N. Almond, Messrs. W. Hunting, F. L. Gooch, H. Cantlon Reeks, T. E. Auger, T. E. Barcham, J. Barr, J. Bee, W. Bower, M. Bray, A. J. Browning, J. Cleveland, J. Hammond, A. Holl, W. W. Kerr, J. E. Kitchin, W. L. Little, T. Love, H. Low, E. Margaron, W. Shipley, S. Smith, sen., H. P. Standley, Norwich; F. B. O. Taylor, W. Waters, and H. E. Wilkinson.

The members first lunched together and the business meeting followed.

NOMINATION FOR MEMBERSHIP.

Mr. ALEC McTURK, of Swaffham, had requested the Hon. Sec., to nominate him for membership as he was a stranger in the district. The President seconded the nomination.

AMALGAMATION OF VETERINARY SOCIETIES.

The HON. SEC. read the following letter:

Royal (Dick) Veterinary College,
Edinburgh, July 8th.

Dear Sir,—I must apologise for again troubling you with regard to the above matter, but the meetings of the National Veterinary Association on the 26th and 27th inst., make it necessary for me to do so. It will not be possible for the Committee to submit a complete report unless a statement of the feelings of the members of the local Societies towards the proposed rules is placed before it and the desirability of the report being a complete one cannot be too strongly emphasised. I would therefore earnestly appeal to you to supply me, if possible, with an official intimation of the result of the discussion by your members of the proposed rules, in order that I may be able to submit it to a meeting of the Committee to be held on the 25th inst.—Yours truly,

A. GORTON, Hon. Sec. of the Committee.

Sidney Smith, Esq., junr., M.R.C.V.S.,
37 High Street, Lowestoft.

The HON. SEC. said the proposal was that each veterinary society should form a division and a certain number of them would form a branch of which latter there would be at least four, two in England and Wales and one each in Ireland and Scotland. Each division would have representatives on the Council which would govern the amalgamated society. There would be one representative for each 25 members with the Secretary *ex-officio*. Thus their Society with about 50 members would have three representatives on the Council. Membership of the National Society could be obtained in two ways. Those who were not members of a veterinary society could join the National direct on payment of 10/6 per annum, or those who were members of a veterinary society through their division for 7/6. Each division would pay an affiliation fee of 1/- per member, and for their 48 members their Society would have to pay 48/- which would entitle them to their three representatives on the Council. Only one of the rules struck him as open to criticism, viz., rule 7, by which every member of the Association undertook to contribute to its assets in the event of its being wound up, a sum not exceeding

21/- any surplus after the winding up to be expended as the Council may direct. The Provisional Committee which arranged the annual meetings would be elected by the Council. On the whole the proposals seemed reasonable and fair.

Mr. MORTON WALLIS said that amalgamation would strengthen their position as veterinary surgeons and as members of their own Society. In a few years something might arise such as had happened to the medical profession in connection with Mr. Lloyd George's Insurance Bill, when if they were banded together they might be able to do something that otherwise they could not do. It would also be useful in other things as it was always difficult to get people in the same profession or business to unite. Amalgamation would strengthen them in any action they might want to take in regard to the County Councils.

The PRESIDENT moved that the Society approved of the amended rules of the National Veterinary Association. Mr. Morton Wallis seconded, and this was carried.

TOOTH SHEARS PURCHASED.

The HON. SEC. asked for instructions as to the purchase of the new tooth shears which were shown at the annual meeting.

Mr. REEMAN proposed that the shears be purchased: Mr. Wright seconded, and this was agreed to.

NEXT MEETING.

The PRESIDENT proposed that the next meeting in September be held at Yarmouth: Mr. Wright seconded, and this was carried *un. con.*

The HON. SEC. said the President would entertain the members to lunch on that occasion.

PRESIDENTIAL ADDRESS.

T. G. HEATLEY, M.R.C.V.S., Woodbridge.

Gentlemen,—It was with mixed feelings that I accepted the office of President for the current year. I felt that it was a very high honour to be asked to preside over you, and I appreciated it very sincerely, particularly in this most notable year of His Gracious Majesty's Coronation, but at the same time I felt hardly capable of fulfilling this important office with the same brilliancy as my predecessors. However, if you will bear with me, and make allowances for any shortcomings I will use my best endeavours to carry out the duties of President of this Association. I wish to thank you most heartily for the honour you have done me.

As a country practitioner I feel somewhat out of touch with many of the big problems which affect the profession, but feel very satisfied with being represented on the Council by a man who has had large experience of town and country practice, and Public Health work; and as he is a capable speaker our interests as country practitioners will not be put in the background. Our very best thanks are due to Mr. Shipley, because attendance at Council meetings involves the expenditure of valuable time, and the outlay of a considerable sum of money. I am sure that if we think of this we shall realize what it means to a busy practitioner to attend the Council meeting regularly, and show our appreciation of his services. I would like to take this opportunity of publicly thanking Mr. Shipley for so ably representing us on the Council.

I think one of the most important matters we must keep in view is the meeting of the International Veterinary Congress in England. I feel that the honour of the profession will be put to the test, and as a considerable sum of money will be required for the entertainment of the foreign delegates, we ought to subscribe annually as liberally as our funds will permit towards a common fund which has been instituted to secure the

means whereby we can entertain members of the profession attending the Congress in a manner worthy of Great Britain. It must not be forgotten that the various foreign Governments, and even members of the Ruling Houses have given their support in grants and even in person, to the Congress when it has met in their various countries. No doubt a strong committee is being formed, who will lay the importance of the matter before the Government.

It seems an invidious distinction to refuse the rebate on the Petrol Tax to veterinary surgeons, and one wonders if those in authority appreciate the work that is being done for the prosperity of the country by members of the profession. As a country practitioner I cannot think that the Chancellor of the Exchequer can know what it has meant to agriculture within the last ten years in one disease alone, namely in the advancement of the treatment of milk fever in cattle. Formerly the percentage of deaths was very high indeed, now it is the exception to lose a case, and in this disease alone it means the saving of thousands of pounds to the country. The disease occurs usually in the deepest milkers, and we as country practitioners know what it means, to one of the Government's pet projects, viz., the small holder, if he loses a cow. It means that one of his main sources of income is gone, and the little ready money which he gets weekly to tide him over the time when his crops or garden produce are maturing is not forthcoming, and we all know that the ready money to these small holders keeps their heads above water. Again, does the Chancellor of the Exchequer appreciate the work that has been done in the case of rabies, foot-and-mouth disease, or pleuro-pneumonia. If these two latter diseases gained a firm footing in the country, previous experience has taught what it would cost to eradicate them, without taking into account the inconvenience caused to the community or the loss in the matter of sale of pedigree stock, for which Great Britain is justly noted, and to which all other countries look in order to procure animals for improving the native breeds. I say, gentlemen, that enough credit is not given to the profession for the part they play in securing the healthy condition of the stock of this country, otherwise the Chancellor of the Exchequer would not have refused the petrol rebate to veterinary surgeons. But perhaps in the light of what has happened, since, in the proposed Insurance Bill, and the great feeling of uneasiness in the medical profession against the clauses which particularly affect them, we must be grateful that we are left alone; and in the face of things I should begin to doubt that if we received some such consideration as the petrol rebate something would follow later that would be distinctly to our disadvantage.

We have before us the interim report on swine fever, and as there must be several gentlemen present who have had considerable experience of the disease at some time or other, either under the present scheme of inspectorships or when the disease was controlled by the various local authorities, I hope they will give us the benefit of their experience, and the conclusions they have arrived at, as it must be a great source of anxiety to the Veterinary Department of the Board of Agriculture, and criticism of the report would be gladly received. As we have the report before us I will make no comments, except that speaking of swine one of the greatest causes, in my opinion, of quacks being a source of trouble in some country practices is that the veterinary surgeon of the district is either unable or won't be bothered with the operation of spaying. In districts where the operation is the custom, as it is in the Eastern counties, it comes to be one of the most important sources of income from some farms, because, as you know, it is no uncommon thing for a man to keep thirty breeding sows or more. If a man sells his pigs, unless

the operation has been properly performed, it means a loss indirectly to the breeder, because buyers will fight shy of purchasing from him again, and in such a case, if the practising veterinary surgeon is not an adept, the local quack will get the work, and we all know that then he will get other work which should be in the hands of the veterinary surgeon. Only last week I was speaking to a farmer who was in the habit of selling to the cottagers in the district one or two pigs each. His pigs had been spayed by a veterinary surgeon, but the operation had been improperly performed, so that the pigs came in œstrum, and to be diplomatic he collected and took back seven sow pigs he had recently sold to cottagers. In a country district there would be nothing more calculated to damage a man's reputation, because the cottager's pig is an important item. We have all heard the student in the palmy college days speak with disdain of the operation of castrating and spaying pigs, but if he means to settle in a country district, where this operation is the custom, he must not deceive himself, and I sometimes think that this disdainful note, both in students and veterinary surgeons, is the result of inability to perform the operation. I think that every young fellow, who thinks of settling in the country, should endeavour to become an adept, because in the present day, when mechanical traction is the fashion, a country veterinary surgeon must be able to take on any work that comes along if his returns are not to diminish. I am sure that if more of the work was done by veterinary surgeons, who appreciate the importance of cleanliness, it would strengthen the hands of the authorities, because I believe many cases of swine disease that are reported as being suspicious of swine fever are conveyed by castrators whose knowledge of bacterial infection is very vague.

As to the Veterinary Surgeons Bill, our hands must be strengthened and our interests protected, and we look to the Royal College of Veterinary Surgeons to do this. But how can they do this if they are in such a financial state that they are forced to sell their already depreciated securities to carry on the work of the College? I cannot understand it. If we have any love for our *alma mater* we ought to support our Council. I cannot understand men standing out and putting every obstacle in the way of the passing of the Bill, because inside opposition is very bad, although healthy criticism is good. In reading some of the criticisms of the opponents of the Bill, I cannot but think that it is pure "cussedness" and an attempt to gain cheap notoriety at the expense of the profession as a whole. If the profession is to prosper, both financially and socially, the Royal College must be in a strong position, with funds at its back to keep up the teaching to the very highest pitch, and to be able to put a check on unprofessional conduct, because such conduct does not improve our position in the eyes of the public. We read of people asking what will be done with the money raised by an annual registration fee. Well, one thing is certain, that it will not be necessary to draw on their capital stock to carry on the work for which they obtained their Charter.

I think that there are few who give more assistance, either financially or by advice, to those who are not too well blessed with this world's goods, than the members of the veterinary profession. My conclusion is that they have got very big hearts, and I should like to impress on you that what should concern us all very strongly are the cases of genuine distress amongst widows and orphans of veterinary surgeons. We in the country know that everything depends on the head of the family in our profession. So long as he has his health things go on smoothly, but let him be laid by, by death or disease, things are very different for those he leaves behind. The professional man in the country has not the opportunity of laying by much store of this

world's goods, and the widow and children in some cases are left in a piteous condition compared with what they have been accustomed to. We have, I am glad to say, members who have instituted benevolent societies for the relieving of distress amongst the widows and orphans of members of our profession, and I am myself directly interested in the Victoria Benevolent Association. Of course we cannot all be on the Investigating Committee who control the distribution of the funds, but I firmly believe that if you could actually know some of these cases, and see the gratitude with which the help of the Society is received, there are none of you present but would assist on the spot, and you can take it from me that none but the really needy receive assistance, and that the funds are distributed to the best possible advantage.

But the principal trouble is that the Association cannot give as much assistance as it would wish owing to lack of funds, and I should like to be able to add to the list the names of all the members of this Society who do not already subscribe, because I know each of you in most weeks of your life do a good turn to some one, and by subscribing to one of these benevolent funds you would be helping those who at some time have been very closely associated with the profession, and are personally acquainted with the worries and hard work of the country practitioner.

I hope all the members will endeavour to be present at our meetings, although I know—only too well—how difficult it is sometimes for a single-handed man to get away. But if it is anyway possible, it does good to get out of the every day rut, if only for a few hours. We can discuss puzzling cases with some friend we see at these gatherings, even if the matter is not brought openly before the meeting, and I should like to see more of these cases discussed openly in a more or less informal manner. Of course I know that it is impossible for every one to attend each meeting, but in order to keep our attendances up to standard we ought to endeavour to get veterinary surgeons who are not already members to join, so that not only would our financial position be improved, but we should then have always a good muster of members at each meeting.

Mr. WALLIS said he would like to propose a hearty vote of thanks to the President for his very practical and instructive address. Mr. Reeman seconded, and the President made acknowledgment.

MORBID SPECIMENS.

The Hon. SEC. handed round some cystic calculi which had been taken from a curly coated retriever at post-mortem. The bladder was also ruptured. The case had been reported at length in *The Veterinary Record* of April 8th.

Mr. REEMAN said he had a similar case in an Aberdeen terrier, which for a long time had difficulty in passing water. The bladder was ruptured, and he took out from 12 to 20 calculi of various sizes.

Mr. HUDSON said a doctor in the town gave him two calculi which he had taken from a smooth coated fox-terrier bitch, two or three years old, which died. They were larger than those shown by Mr. Smith.

The PRESIDENT said that at the last meeting at Bury he read a paper on the removal of a foreign body from the penis of a foal. That horse was shown at the Royal Show at Norwich and got a "Commended" or "Highly commended" mark, but it had never been any trouble since. He found the foal crouched down trying to get rid of its urine. The obstruction was eight inches from the orifice, and when he drew out the latter organ he could locate the stone quite well. He cut a small opening through the lower part of the penis, and a larger one in the urethra. As soon as he cut into the urethra there was a tremendous outflow of urine which could not pass fast enough through the external opening and the penis

expanded until it was nearly as big round as his leg. He recovered the stone, and naturally expected trouble through the urine escaping into the penis, but he only saw the foal once or twice, and the hole in the urethra healed up quite satisfactorily. He did not put in any sutures. The calculus was about $\frac{3}{4}$ of an inch long. He sent it up to the College and was informed that the nucleus was epithelial cells and an accumulation of triple phosphates round it.

Mr. GONBOLD said he was called to a bull which he imagined had gravel all the way up the urethra. He had thought of cutting a hole just below the anus and inserting a tube into the bladder so that the bull could be fattened up, but he died. In the bladder were calculi as large as walnuts.

Mr. TURNER said he had operated on fatting bullocks and young stock for this trouble, but he never had much success. He had recently had a couple of cases out of one stable which had rather puzzled him. The first was a roan cart gelding, a very free and active horse, which was noticed to get into a sort of sleepy, drowsy state. If taken out of its stable and left it would stand asleep. The horse showed symptoms of cold, had a temperature and intermittent pulse, and it seemed as if influenza was coming on. There was some brain symptoms and the horse was very yellow about the membranes. It seemed to get better, but there was still a nasty colour about the membranes. He (Mr. Turner) began to think the liver was the trouble and gave some physic under which the horse improved, so much so that he ordered it to work, but at night he was sent for and found the horse in a very bad way in its stable. It could not get up, and nothing could be done with it. Next morning it was standing in its stall perfectly rigid, and neither whipping nor pushing would move it. He suggested a second opinion, but the agent was for turning the horse out and letting it take its chance. He then asked Mr. Reeman to look at the horse, but in the meantime the owner said he would not have any more doctoring but would make up some balls, and if they did not cure the animal it must be slaughtered. It was eventually sold to a slaughterer, who bought it to go abroad. He heard that they had great difficulty in getting it along, and whether it ever got to its destination he never learned.

A horse from another farm took its place and stood in the stall. After it had been there a month or six weeks it developed similar symptoms. It had not such a drowsy appearance as the first animal, but it had a temperature of 103, mouth very hot, and some discharge from the nose. It was put into the same box and treated for cold, but did not seem to get on, and had the same drowsy appearance. The fever went down, and a dose of physic was given which operated sufficiently well. The pulse went down to 33 and stuck there, and the temperature was 99. When taken out and moved about one might think there was not much the matter with the horse. He ordered it into a paddock to develop the brain symptoms. It was put to graze, but for how long nobody knew because the next heard of the horse was that it was in the canal with the water over its back leaning up against an island. It had walked over an iron fence 3ft. high and gone straight into the water to this island. With a great deal of trouble it was got out, taken home and treated in the box. It continued to have low pulse and low temperature, but the brain symptoms became more aggravated. The horse died pressing its head against the wall of the box. It was taken to the kennels where he made a post-mortem in conjunction with Mr. Reeman. This horse had shown no lung symptoms, except at first when it had a cold, and mustard was applied to the sides. But from the top of the larynx and down the trachea was extensively inflamed. Both lungs were very much inflamed and congested. The other organs seemed

quite healthy. On opening the brain there was a small effusion of a yellowish colour in the front portion, but very slight, and they could see nothing radically wrong—nothing that might have been expected. He was greatly puzzled as to the cause, but came to the conclusion it was the result of gas from an electric lighting plant, fixed up just outside the stable, which was a very bad one, lying very low and very badly ventilated. The horses slept in it all night, and as the people were not particular about cleaning out the manure there was plenty of ammonia. The electric light plant was close to the stables, and in consequence some boards were knocked out to give ventilation to the stable. This was just on the line whence the poisonous gas came. The engines were worked from 5 p.m. to 11 p.m., and the men had complained constantly of this gas and of the choking sensation it caused. Notices were put up in the engine-room as to the poisonous gas given off in the first instance. The gas was made from anthracite coal. He had been unable to ascertain its nature, and the firm who supplied the plant had written that they were unable to inform him until their managing director returned. According to what he could make out it was carbon monoxide, and he wondered if any member had had a similar experience. In the stable the first horse stood so that the gas passed over him, but the second horse caught it. The third horse was protected by a partition, and then there was a shaft where this exhaust gas was taken away. He could not account for the trouble in any other way. Formerly this gas used to be taken out by a long pipe, but recently it had been allowed to come into a pit, and it was made so that there was an escape more or less from this pit. The first gas that came off at starting was very poisonous indeed. It was difficult to prove, but it was very singular that two cases should occur on the same farm, and both horses stood in the same stall.

Mr. REEMAN said the lungs he saw at the post-mortem were in a very bad state, and one was simply black right away from the larynx downward, the mucous membranes were of the same colour and intensely congested. The liver was rather small but quite healthy, stomach all right, and also the intestines. With the exception of the lungs there was nothing in the viscera to account for the trouble. In the anterior portion of the brain was a straw-coloured fluid, but the brain was healthy, and he could find no tumour, though both horses looked as though they had some tumour of the brain. He was inclined to think with Mr. Turner that gas was the cause of the trouble. The stable was one of the worst, as there was absolutely no ventilation. This exhaust gas came quite down into the stable, and being heavy it would sink down, so that the stable was practically steeped in it all night.

The PRESIDENT said it was a very interesting case, and they were much indebted to Mr. Turner for bringing it forward. The gas was probably the trouble, and if the horses had inhaled it for some time the blood would be affected, and then the whole of the nervous system. The effusion on the brain would account for the boring of the animal's head against the wall.

INTERIM REPORT OF SWINE FEVER COMMISSION.

The HON. SEC., who opened the discussion on this subject, said the first thing that struck him was the list of people who gave evidence. The number the veterinary surgeons was surprisingly few, five in all, and three were connected in some way or other with the Board of Agriculture. The remaining two were practitioners, veterinary inspectors. He did not know whether either of these two gentlemen had much to do with the castration of pigs or not. There seemed to be no one called who was largely in touch with castration, though this was a most important item in the treatment of the disease, because the pig cutter was considered to be an

agent in carrying the disease. Otherwise the evidence was fairly representative; there were different authorities on various subjects who gave a great deal of useful evidence.

The number of confirmed outbreaks was fairly steady in spite of all the efforts made to eradicate the disease. In 1910 it was 1598, in 1909, 1650; in 1908, 2067; in 1907, 2336; and going a few years back in 1905 it was 817; in 1904 it was 1196; in 1903 it was 1478. Success was not therefore very apparent.

It was a question whether the local veterinary surgeon with his knowledge of the people and the conditions was not as well qualified to deal with the disease as a special inspector. If local practitioners were taken into account and sympathy accorded them more progress would be made.

In regard to the compulsory inspection of markets, the report stated this was carried out either at the entrance or in the pens, and he would like to know from gentlemen who were inspectors for local authorities which method they considered most satisfactory. Remuneration was a variable quantity, and while it was most desirable it should be fixed there ought to be a sliding scale according to the number of pigs or the hours put in at a market. At present it seemed to depend upon the caprice of the auctioneers. Perhaps the recommendation of the Committee that payment should be made by the local authority would have some effect.

Compensation for slaughter no doubt entailed great expense, but it was very desirable, otherwise swine fever would always be with them. At present the regulations pressed very hardly upon the man whose premises were isolated, and did not constitute a danger to anyone else. His pigs were not killed and he got no compensation, whereas if they were in a position to be a source of danger his pigs would be killed and he would get compensation.

A point raised by the Commission was the registration of operations by castrators. This was more important in the case of unprofessional castrators going about with no thought of cleanliness or of contagion. In some places the owners of boars and pig dealers kept registers, which must be a great help in tracing outbreaks. The crux of the whole thing was that there must be sympathy and accord between all persons affected—between the pig keeper and the local V.S., and the Board of Agriculture. If that could be arrived at the problem would be solved; there would be no more friction, and swine fever would be stamped out.

The PRESIDENT said that judging from the witnesses called, the Departmental Committee might have been trying to get the opinion of the general public more or less. They knew the opinions of the profession, and this might be some explanation why more V.S.'s were not called.

Mr. WRIGHT said his firm opinion was that swine fever was more or less spread through sales and markets which were not kept so clean as they might be. A farmer who found he had swine fever did not report but sent his pigs to some sale. He never knew it to break out spontaneously—it was always conveyed. He had castrated pigs for 45 years and had never known a case of swine fever except what was brought on to a farm. Where one went on a farm to which no pigs were brought, there was no swine fever, but it was often contracted when sows were taken away to boars.

Mr. GODBOLD said he had known several cases where it had broken out apparently spontaneously. He had known it to occur on farms where no pigs had been brought.

Mr. WALLIS said there was no doubt that the public were disinclined to report swine fever if they could help it. Many of his clients, if they had a pig ill or dead, sent for him in the first instance to ask what was amiss

before anything was done. If there was the least suspicion of swine fever he recommended them to report it at once. If a V.S. was sent for he had a perfect right to make a post-mortem, and was not in any way straining the law in so doing. Last week he was called to a pig that died and found the castrator had attached the bowel to the scrotum with the inevitable result.

There was certainly a good deal of friction between the local V.S. and the Board. A local V.S. if qualified to diagnose swine fever should be allowed to deal with it. There was no inducement to help the Board of Agriculture had been inspector of his market for two or three years, and it made a lot of difference. It was better for the auctioneer and better for the public, because pigs popularly called "rotters" were not sent when it was known he was going round to look at them. In the ordinary way he got 5/5 for the inspection every Tuesday, and if there were over 200 pigs he had 10/6. It was a very poor fee for examining a lot of pigs. It was paid by the County Council. Until they were all united by joining the National they would never get better fees. The proper way to stamp out swine fever was to get farmers, veterinary surgeons, and all interested to co-operate, to slaughter right out and compensate. Registration of castrations might prove a help, but he could not recall a case that had arisen in this way.

Mr. HUDSON said he thought a local V.S. if called to look at some pigs which had died was perfectly justified in making a post-mortem. It was a great inconvenience to a farmer to report his swine, especially at such times when he had fat pigs he wanted to send to market, as he might miss his market during the time he was shut up. A V.S. could help his client very much by going and giving an opinion. Swine fever was greatly spread through the markets and by pig dealers who should be licensed, like hucksters, and have to keep a register where they sent pigs. This would greatly simplify matters. There were plenty of dealers who would go and buy 200 or 300 pigs, bring them to their place and then distribute them all over the country.

Swine fever could break out apparently spontaneously where pigs were badly kept and in badly managed farmyards. Some of these were very badly drained, and not at all fit for pigs or anything else. They were losing many pigs in his district from broncho pneumonia which was killing as many as swine fever. It was very contagious, especially amongst young pigs.

Mr. REEMAN said it seemed to him that the disease was losing the virulent character it used to have; he came to this conclusion from frequently making post-mortems. Sometimes he found the acute form in only one or two pigs, and if the remainder were properly isolated they did not get it at all. Formerly one might feel certain all the rest of the pigs would get it if they were left. Pigs kept in bad sties would get into such a debilitated state that they were more likely to take the disease. There could be no doubt that infection must be conveyed. The disease could not arise of itself. He thought all pig dealers were now compelled to keep a register showing where they bought and sold pigs. He had found it the rule in Norfolk and in parts of Suffolk. One drawback was that the public were so loth to report. Under present conditions, where an infected area was confined to only one set of premises, the public should co-operate with the authorities more than they do by reporting outbreaks. The law was that when any illness was seen in pigs it should be reported at once, but unfortunately this was not always done. Payment for inspection should be under the control of the local authorities, not of the auctioneers. Undoubtedly the disease was conveyed by castrators who very often were blameless, because animals might have the disease quite badly enough to convey it to others without showing any outward symptoms of a serious disease being carried. He was a thorough believer in cleanliness, espec-

ially as to the knife and the needle. He had repeatedly seen swine fever on farms where they bred their own pigs, and had found a big outbreak where a pig had never been carried on to the place. This pointed to infection being carried some other way. In some cases it had been the greatest possible difficulty to trace, and they never had traced it, although they had made every enquiry, unless it had been carried by food. He was of opinion it could be carried by food, and especially where a lot of foreign food was used. He was convinced slaughter was the only means by which they could hope to extirpate the disease, though he feared he was inclined to take a pessimistic view. Swine fever was here, and he did not think they would ever get rid of it. One fruitful source was very bad sties. It was impossible to disinfect them, and the only thing would be to burn them down, but the owners would not agree to that. He did not believe at all in the isolation theory, and thought the only remedy was slaughter, but the owners ought to be compensated.

Mr. P. TURNER said that the reason farmers lost confidence was because so many mistakes had been made at the Board of Agriculture. He had two cases of pigs suffering from salt poisoning due to butter milk. In one case it was said to be swine fever, in the other not swine fever. In another case of a pig injured on a farm he had under the old system to send up the lesions. An inspector was sent down, who condemned the lot for swine fever. The farmer would not have the pigs slaughtered. The inspector came down in a fortnight's time, but no more pigs died. In another fortnight there was a large increase of young pigs but none died, and by and by the man was left alone. The Board was too careless in shutting up places.

The PRESIDENT said his experience had not been extensive. As he went about the country he formed the

opinion that most of the outbreaks were due to pigs bought in the markets. Then a lot of cases arose from pigs bought of certain dealers. If there were some method by which they could be prevented from dealing in screw pigs it would be helpful. Where it could be proved that they wilfully bought unhealthy pigs from farmers and exposed them for sale in a public place, they should be severely punished. Some members had confirmed the view that castrators carried the disease from one place to another. The local authorities should do something with regard to indoor sties. With the outdoor sties there was a natural process of disinfection going on, but all indoor sties should be made subject to thorough disinfection.

This closed the discussion, and the usual vote of thanks to the President concluded the meeting.

SIDNEY SMITH, JUN., Hon. Sec.

The University of Liverpool.

The Royal Lancashire Agricultural Society have awarded medals to the following students of the Veterinary School:—

Gold Medals:—*Class A*: C. W. Elam. *Class B*: R. H. Knowles. *Class C*: W. P. Stokes. *Class D*: J. R. Barker.

Silver Medals.—*Chemistry and Physics*: J. A. Ward. *Biology and Junior Anatomy*: C. W. Elam. *Senior Anatomy*: R. H. Knowles. *Physiology*: R. Isherwood. *Stable Management*: H. Sumner and V. A. Bartrum. *Materia Medica*: S. K. Jones. *Pathology, Bacteriology, Hygiene and Dietetics*: G. G. Howard. *Medicine, Surgery, and Meat Inspection*: C. W. Makinson.

NOTE.—The figures for the Current Year are approximate only.

* As Diseased or Exposed to Infection

Foot-and-Mouth Disease at Rye.

On Sunday, Lord Carrington, President of the Board of Agriculture, accompanied by Lieutenant-Colonel Sir Edward Clarke, one of the superintending inspectors of the Board, conferred with some of the largest graziers in the proscribed district. He has decided, should there be no further outbreak of the disease, to issue on Wednesday next an order which will enable the removal by licence forthwith of sheep and cattle for slaughter within the outer parts of the scheduled area, including Romney Marsh; and a further special order will also be issued under which fat sheep may be sent alive out of the same outer district by special trains to the Foreign Animals Wharf at Deptford—an arrangement come to through the courtesy of the City Corporation. It is hoped that by these means some part of the inconvenience suffered by flock-masters may be overcome. The arrangements for the removal of sheep will be in the hands of the Board's inspectors at Rye, who will personally inspect the animals on their respective farms before entraining. This concession will not be extended to cattle, and the sheep on arrival at Deptford will be in charge of the officers of the Foreign Animals Wharf until they are slaughtered.—*The Times*.

The Milk Supply of Melbourne, Victoria.

Recognising the necessity for keeping this nutritious and necessary food up to a proper standard of purity, the Victorian Legislature passed laws to control both its production and distribution. Every farm that produces milk for city supply, including the cattle, fodder, water, and utensils that are used in connection with the dairy work, is under strict supervision. The milking cows are subjected to systematic manual examination by officers trained to the work; and, should any not be in satisfactory health, they are prohibited from use temporarily or permanently, according to how they are affected. The carriage and subsequent distribution of the milk is also under supervision by this same staff. The distribution is under the surveillance of another staff, whose special province it is to sample the milk as a check against its being adulterated. Samples are taken on the farms, on railway stations, and from dairies or milk waggons, at any hour of the day or night; and any one found selling an inferior, adulterated, or otherwise unwholesome product, is prosecuted forthwith. Consequently, it is likely that no food product is of a more satisfactory grade of quality than the milk supplied to those cities and towns of Victoria where the Milk and Dairy Supervision Act is enforced.

Not only as an administrative movement, protective of the public health, but as an economic proposition that has benefited largely those who are engaged in the business concerned, this Act stands out prominently as an example of successful legislation. It came into force in the Metropolitan Area in July, 1906; and the officers intrusted with the carrying out of its regulations had the task before them of raising the standard of the production and distribution of the milk supply, while at the same time it was incumbent on them to effect that result as economically as possible for the dairymen. As might have been expected under such divided control, or want of control, as previously existed, they found dairying being carried on under very varying conditions. A few places were fairly satisfactory. In some others, a little better attention to sanitary detail, and some inexpensive constructional improvements, were all that was asked for. But there were certain places where the conditions under which milk was being produced and handled were vile. These latter conditions were found to arise from ignorance, carelessness, and, in some cases, even from wilful disregard of reasonable cleanliness. Under advice, admonition, or threat of prosecution, according to their respective class, many of these keepers of in-

sanitary dairies improved both their premises and condition of working; and ultimately received the statutory licence which marks premises as satisfactory. A few others are still on the "withheld" list, which indicates that while their premises are not insanitary, they have not been kept consistently satisfactory. Those who either could not, or would not, improve in their methods, have had their application for licence refused; and in such cases further sale results in prosecution.

The scope of this Act is sufficiently comprehensive to include under its provisions all premises from which milk is distributed in even the smallest quantity, either through sale or barter. Where any such disposal of milk takes place, a licence fee must be paid, and the premises and stock inspected. The giving of milk in return for fodder or other commodity, for cattle pasturing, for services rendered, or any other sort of barter, is equivalent to a sale, and a licence must be applied for.

Before the Act came into force there were many so-called private people who kept from one to several head of cows, ostensibly for the purpose of supplying their household with dairy produce. When surplus milk was on hand they sold to their neighbours; and, in order to gain custom, it was too frequently sold at a price much lower than that charged by the dairymen. The bulk of this private milk selling took place in the spring when grass, and, consequently, milk also, were most plentiful. At other seasons these people usually had only enough for their own requirements, for their cattle had generally to sustain themselves on such scanty grazing as might then be found on the unfenced suburban allotments.

In order to hold trade, a legitimate dairyman must maintain a regular supply of milk to his customers the year through; and during the autumn and winter months he frequently does this at considerable expenditure for fodder for his cows. During the spring and early summer months, when milk is plentiful and comparatively cheaply produced, the dairyman expects to recoup himself for the extra outlay incurred in keep up the supply during the months of scarcity. Should he, however, meet with competition from unlicensed people, who, by underselling him in the spring, reduce his trade at that season, his case is hard; and much of this actually occurred before the advent of Government supervision.

Some few years ago the dairying business was rendered very unsatisfactory through the number of men who carried on "cutting" or underselling of their trade competitors as a regular procedure. At this time it was generally supposed by those in touch with the trade that "cutters" were also sellers of inferior quality milk. Subsequent events showed this conclusion to be correct in numerous instances; for the samples of their milk taken in the course of its distribution resulted in repeated prosecutions, until finally they either sold good milk at the usual price or went out of the business. With the abolition of unlicensed cowkeepers and those whose premises were kept in an insanitary condition, and through the sale of inferior milk at low prices having become unprofitable to the cutting fraternity, dairying as a business has greatly improved during the past five years. Those who were at first opposed to central supervision are now its strongest supporters; and many dairymen freely acknowledge that the Government system of supervision has been the making of their business. One of these, a large trader, volunteered the information that for several years prior to its inception he had barely held his own in trade competition; but, during the three years following the Government taking over the supervision, his business increased over 30 per cent., and it has kept on improving.

THE BUTTER FAT STANDARD.

Regarding the 3·5 per cent. butter-fat standard, as fixed by the Pure Food Standards Committee, some

retailers aver that it is unreasonable high ; but a large majority are satisfied with it. A most significant fact in its favour is the very small number of milk samples taken that have been below the standard. It is still more rare to hear of a retailer with his own farm selling inferior milk. Such dairymen are most emphatic in their approval of the standard. The quality, purity, and freshness of their milk all combine to bring them trade, and they can readily sell all they can produce. At the same time, it is recognised that in the spring flush some cows do give milk that is not quite up to standard quality during at least a short period after calving ; and if there were many such freshening in a herd at the same time, the owner might be called to account on the quality of his milk as estimated on its butter-fat content. There is little chance of this occurring where a farmer keeps up a regular supply of milk the year through, and arranges that his cows will freshen at different months throughout the year.

Many retail dairymen who are supplied by several farmers pay a retaining fee for the services of an expert analyst who tests the milk of each supplier as often as may be required. Should any fault be found the dairyman can then take steps for his own protection. Mis-statements are, however, known to occur in this connection. On one occasion, a farmer, being informed by his retailer that his milk was not up to standard quality, applied to the Board of Health for his milk to be tested on the farm. This was done, and from over thirty samples taken at different milkings there was an average result of 4.5 per cent. of butter-fat ; and none of the samples went below 4 per cent. Evidently a misstatement or deliberate adulteration had taken place somewhere ; but at least the result exonerated the cows. Those dairymen who retail milk from their own herds find no necessity for retaining the services of an analyst, as the standard does not cause them any uneasiness.

COOLING ON THE FARM.

The most common complaint retail dairymen have against their farm suppliers is their lax methods of cooling in hot weather ; and many a farmer has lost a good customer through carelessness in this matter. If carefully carried out, the usual cooling on the farm by means of well water running through a cooler will bring milk down to the required temperature. In the colder months, the temperature of the atmosphere assists in this work ; but in warm weather it retards it, and this point is often overlooked. In warm weather, the milk should be passed very slowly over the cooler in order to take full advantage of the cold water ; and if the heat is not taken out of the milk in one cooling, it will pay to run it over again. This second cooling will reduce it to the temperature required ; and it will have a chance of reaching the retailer in a satisfactory condition. When a farmer contracts to supply milk he should do his best to see that the buyer gets it in good order. It is unreasonable to expect payment for milk that cannot be sold ; and to get such milk from a farmer disorganises a dairyman's trade, causing him not only loss of time but also of custom.

One of the principal advantages of the refrigerator to the dairyman lies in the facility given for the quick and thorough reducing of the temperature of the milk by use of the brine cooler. Once cooled, it is not a difficult matter to keep milk cool, but, as mentioned, if this is not done quickly the milk soon spoils. With brine cooling, it is usual to reduce the temperature of the milk to about 45 degs., and maintain it at that, or lower, in the ice-room until sent out for distribution.

MILKING METHODS.

Another subject that has caused discussion among those interested in the fresh milk trade is the comparison, from a sanitary standpoint, of machine and hand milking. Either method may be bad and both methods may be good. If kept scrupulously clean, the machine

has an advantage over hand-milking, as it conveys the milk under protection of the tubes from the udder of the cow to the covered receiving bucket : thereby removing all risk of its being contaminated by flies, dust, or other dirt. In order to be satisfactory, hand milking calls for unremitting care in keeping the cows well groomed, and the milking shed and surroundings free from accumulation of dirt of any description. It is impossible to keep cattle in a perfect state of cleanliness in all weathers and at all seasons. This is universally recognised ; and therefore those milking conditions that were the best possible under existing circumstances have in the past been considered satisfactory. With the improvements that have been made of recent years in milking machines, they have reached a standard of efficiency that has brought them into fairly general use in many districts ; particularly where the scarcity of labour had previously been a hindrance to dairying. With their use the standard of cleanliness in milking has been raised much above what previously was the best.

The work of retailing milk under the individual owner system, as at present in vogue, is often spoken of by observers as being very expensive to the dairymen on account of the great area that is travelled over by each cart in working the several rounds. Among the many suggestions that have been put forward for remedying this are municipal, co-operative, or large proprietary depots, from which the whole of the milk for each suburb, or group of suburbs, might be distributed ; the carts each delivering to all the houses on a given route. This would certainly do away with much of the travelling that the present rounds call for ; but it would also close out all competition and individual effort, which very probably would not be to the benefit of the public. As matters now stand, they have a choice of several dairymen in every district, both in regard to hour of delivery or individual fancy in quality of milk supplied. Every dairyman also has some customers whose trade he values so highly that he would go a long way out of his usual route to serve them. It is in following customers such as this who have moved to another locality, that a dairyman often increases his round, as their recommendation will bring him more trade. Taking everything into consideration, the present working system appears to be fairly satisfactory for both consumers and suppliers.

The Model Dairy, owned by Messrs. Simonton Bros., of Kew, is one of the oldest and best arranged of the modern dairy outfits. It stands on a 3-acre block in Belmont Avenue, where the business has been established for fourteen years. The refrigerating plant was installed five years ago. This place handles 1575 gallons of milk, and 1000 pounds of butter weekly. The butter is from one of the best Victorian factories ; and is printed specially for this retail trade. The milk is produced on two farms near the outer boundary of the suburb, and is brought in from there, morning and evening, by the dairy waggon. As it is milked it is passed over the cooler, and is ready for transport to the dairy within a few minutes after the milking is finished.

Two dairies which do the largest business, and which have also been the longest fitted up in regard to refrigerating appliances, are those of the Willsmere Certified Milk Co., in Bourke St., Melbourne, and Messrs. Larcher and Sons, of Moor Street, Fitzroy. Between them, these firms handle about 18,000 gallons of milk weekly ; and to supply their *clientèle*, numbering in each instance upwards of 3,000, they carry a large vehicular equipment and staff of employés. The supply of each is drawn from several districts, and from numerous farms. Members of both firms are well known in every milk-producing district supplying the metropolis ; for both make a point of inspecting the farms from which they draw their supplies. (From *Journal of Dept. of Agric.*, Victoria, by J. S. McFadyean, Dairy Supervisor.)

Tuberculous Cow—Farmer Summoned.

At Coventry Police Court on July 17th, Alfred Henry Blyth, Binley Grange, Binley, was summoned that being a dairyman who supplied milk within the city of Coventry and had at his dairy at Binley Grange a certain cow exhibiting signs of tuberculosis of the udder, failed to give written notice of the fact to the Medical Officer of Health contrary to the Coventry Corporation Act, 1900, section 45.

Mr. W. Maddocks, for defendant, pleaded not guilty.

The Town Clerk (Mr. G. Sutton) was for the prosecution, and said that the proceedings were for non-notification to the Sanitary Authority that the cow in question exhibited signs of tuberculosis of the udder.

Mr. C. H. Wood, of the Town Clerk's office, produced the official notice of the publication of official notices as required by the act.

William Henry Clarke, Inspector of Nuisances, stated that on Thursday morning, May 18, he was near the Bull's Head Inn, Stoke, and saw Mr. Blyth with a churn of milk in a float. Witness took this sample of milk for chemical analysis, and then he obtained a specimen of mixed milk from this churn for the purpose of bacteriological examination to ascertain if the cows were giving tuberculous milk. He informed Mr. Blyth of the object of this sample, and witness submitted it to the Birmingham University the same day for the purpose of examination for tubercle bacilli. The same afternoon witness was in Bishop Street and saw a dealer named Westley in the employ of Charles Hyde, butcher. The man called witness's attention to a cow that was in the stable in the Bull and Anchor Yard, Bishop Street. The cow was extremely emaciated, and with a very large, irregular-shaped udder. Witness felt the udder; it was very hard and knotty, and it appeared to be tuberculous. It was the largest udder he had ever seen, and of most irregular shape. He called at Mr. Hyde's stable the same afternoon with Dr. Cates, who examined the udder. Witness subsequently arranged with Mr. Hyde to have the cow killed in the stable owing to its weak condition, the animal being unable to move. He visited the stable on the following Monday morning and saw the cow dead on the floor with the skin partly removed. Witness examined the organs and found them badly affected with tuberculosis. He caused the udder to be removed wholesale to the rear of the Health Department, Hay Lane. He cut into the udder in company with Dr. Snell the same day and found them full of old-standing tuberculous disease. Since that day he had visited Mr. Blyth's farm, but did not see Mr. Blyth. He met him in Bishop Street on June 24, and Mr. Blyth then stated that the milk from his old cow had not been used with the milk for a fortnight.

Mr. Maddocks cross-examined witness as to his definition of a dairy, and he replied that in the ordinary sense he thought it meant where milk was stored after it had been milked from the cow. It included a cow shed. Mr. Maddocks said that the cow in question had not been in a cow shed for milking purposes for over a fortnight previous to the 18th of May.

Mr. Maddocks: Could anybody in the world say without making a thorough and internal examination of the cow if it is suffering from tuberculosis? Witness replied that they could see that the cow exhibited the most visible signs. It was like a bag of bones, extremely emaciated, its udder was very irregular in shape, and it was six times as large as a normal udder.

Dr. Snell, Medical Officer of Health, thought that anyone could see that the udder was diseased, and that anyone knowing anything of cows should have suspected tuberculosis.

Dr. Cates, Assistant Medical Officer of Health, also gave evidence as to the condition of the cow and the state of the udder.

Mr. W. Dale, veterinary surgeon, said he saw the cow after death, and noticed the udder. He thought an udder in such a condition as this should have made one suspicious. He thought the cow must have been suffering from tuberculosis for some time.

John Westley, dealer, St. Agnes Lane, spoke to fetching the cow from Binley in accordance with instructions. He said the cow fell down on the way to Coventry, and he was obliged to procure a float to bring her to the Bull and Anchor Yard. Witness called Mr. Clarke's attention to the cow the same afternoon, and the animal was slaughtered the following Monday. Witness referred to the huskiness of the cow on the journey to Coventry, and said that this, combined with the size of the udder and its condition, led him to think that it was tuberculous. In reply to the Town Clerk witness said he drew milk from the cow the same day that he removed it, and the milk came freely.

Charles Hyde, butcher, Well Street, said Mr. Blyth asked him to send for a cow that had a bad leg. Witness asked him if it would travel, and he said "Yes." Witness sent the witness Westley out to fetch the cow, and on its arrival witness saw it. It was hardly a bag of bones, but the cow was not good enough for him. There was something the matter with the cow or it would not have had such a large udder.

By Mr. Maddocks: The cow was never intended by Mr. Blyth for food. When Mr. Blyth saw him about the cow a fortnight previously he told him to do the best he could with it.

Mr. Maddocks addressed the Bench for the defence, and submitted that no notice under the Act was given to his client. He admitted that notices were published, but such did not come to the knowledge of the defendant. Then as soon as anything was found to be wrong with the cow, defendant placed it apart from the other cows and kept it away from them. Mr. Maddocks further submitted that defendant's farm was not a dairy within the provisions of the section of the Act.

Defendant said his farm of 250 acres was a mixed one. He had sixteen or seventeen cows. A little milk was sold at the house for those living in Binley. The remainder was sent to Coventry. He had told Mr. Hyde about the cow, which had not been in the cowshed for some two or three weeks before it was fetched away. It was a common thing to have enlarged udder. He gave instructions that the cow in question was to be "dried off," and that under no circumstances was the milk from her to be put with the other milk. He had the cow put in another part of the farm, thinking that she might improve. He had never received notice to the effect that he was to report to the authorities a cow that might be suspected of having tuberculosis. He did not suspect this cow had tuberculosis. He thought possibly it was suffering from inflammation of the udder. He was quite prepared to allow a veterinary surgeon to inspect his herd of cows and to take samples of the milk. He would be only too pleased for this to be done. He admitted that the udder of this particular cow was enlarged. It had all come about since the beginning of April.

The Bench held a consultation, at the close of which the Chairman (Mr. T. B. Bethell) intimated that they had come to the conclusion that, on the evidence, there must be a conviction. The penalty would be 20s. and costs.

Mr. Maddocks said this was the first case of the kind that had been brought before him, and was so important that he should ask for the recognisances to be fixed pending an appeal. The Bench fixed these at £10.—*Midland Daily Telegraph.*

The Bank of New South Wales, the oldest banking institution in Australia, has removed from Old Broad Street to its new offices at No. 29, Threadneedle Street, E.C., London.

Personal.

Mr. AINSWORTH WILSON, recently appointed to the Chair of Surgery and Obstetrics at the Royal (Dick) Veterinary College, is at present in practice at Witham, Essex. He distinguished himself as a student of the Dick College, from which he graduated in 1894, and he obtained the Fellowship Degree of the Royal College of Veterinary Surgeons in 1903. After some time spent in Bombay, to which he was sent out by the late Prof. Walley, Mr. Wilson returned to this country, and he has held several public appointments in England and Scotland under the Board of Agriculture and in connection with the administration of the Public Health (Scotland) Act.—*N. B. A.*

Mr. HAROLD AUBREY, M.R.C.S., L.D.S., has been appointed Assistant Dental Surgeon to Guy's Hospital.

OBITUARY.

CORNELIUS CUNNINGHAM, M.R.C.V.S. Slateford, Midlothian. 1859. Graduated, Edin: April, 1880.

Mr. Cunningham died at his residence on the 22nd inst., suddenly, after a long illness. Aged 72 years.

CORRESPONDENCE.**ANTHRAX IN GOATS.**

Sir,

Those who have observed cases of anthrax in goats state that the disease is rare. The cause of the complaint in them has been ascribed to food grown on anthrax-infected ground (where carcasses have been buried). The symptoms are convulsive, reeling, tumbling, and staggering movements as well as blood discharges from the orifices of the body (Dr. G. Wilsdorf). Hutvra and Marek state that the disease is rare in goats, and other authors who write about caprines do not mention the illness.

It would be interesting to know if Mr. Page can give any reason for the "cessation of the disease for 14 months."—Yours truly,

G. MAYALL.

OBJECTORS TO THE BILL.

Sir,

So poor dear Mr. Dyer has thrown up the sponge in wrathful mood, and says he will take no further notice of my "libels" unless they cease to be anonymous—and I note that he is careful to make no definite promise to answer me even in that unlikely event. Unlikely it is, for I see no earthly reason why I should abandon my anonymity. If I really thought that the publication of my name would induce either Mr. Dyer or his allies to make some serious attempt to establish the entity of that opposition of 900 members—well, in that case, I might be tempted. But I do not think that they would dare to do anything of the sort—does their behaviour up to the present look like it? Mr. Dyer himself, after a ludicrously feeble show of fight, has adopted a policy of scuttle; and, though he endeavours to impart dignity to his retreat by reviling me over his shoulder as he runs away, I am afraid that his language only renders the completeness of his discomfiture more evident. His four heroic confederates, wiser than he, have kept as quiet as mice all the time, and have not ventured to say a word for either themselves or their circular. In fact, the whole blessed Committee, "not loving the light," is trying to hide itself away as best it can, for fear people should find out exactly how small it is; and that Mr. Dyer should invite me to "come out of my hiding" is a suitable climax to the grotesque absurdity of the whole proceeding. It was fitting that an anonymous writer should demolish this fiction of the existence of 900 opponents of the Bill, for, if there had been any difficulty in the undertaking, an anonymous writer would have been least

likely to succeed it it. Well, I have succeeded—but have I encountered any difficulties in the way? I think not—in fact I have found it such an easy task that modesty prevents me from personally coming forward to claim credit for it.

Nine hundred members opposed to the Bill—the idea! Everybody knows that the Bill could never have been presented to Parliament if there really were 900 members opposed to it—no one would have regarded such a statement seriously, if only it had been made within the profession. But the statement was made without the knowledge of the profession, and made in the hope of influencing M.P.'s who would probably see nothing incredible upon the face of it. That being so, I thought it well to demonstrate its indefensibility in the most widely-read of our professional journals; and I think that—thanks partly to the valuable assistance Mr. Dyer has given me—such demonstration is now as complete as could be wished. And so, for the present at least, in Mr. Dyer's own words, I "am content to leave judgment in the hands of all honest men." What a happy knack Mr. Dyer has of coining phrases which are capable of being throw back to him with dire effect to his own side!—Yours faithfully,

"MEPHISTOPHELES."

PROFESSIONAL FEES.

Sir,

I was much interested in the report in last week's *Veterinary Record* of the South Durham and North Yorkshire Veterinary Medical Association's special meeting, called "for the purpose of discussing professional fees, and the desirability of some uniform scale of charges being drawn up."

The necessity for such uniformity is not confined to the North of England. Some weeks ago I summoned a client for payment of an account against him for treating his cat in my infirmary, his defence was that my fees were exorbitant (I had charged him my minimum fee of 10/6 a week), and that he could have his cat treated in a veterinary surgeon's infirmary for 4/6 a week. I ventured to express considerable doubt as to the veracity of this, but was silenced by the production of the receipt.

I wrote to the firm in question, a firm occupying a prominent position amongst London veterinary surgeons, living and practising in the West End, and was courteously informed that they did take in as patients cats for 4/6 a week.

Personally, I cannot understand the reason for this, even from a business point of view. I have been in practice in West London for over twenty years, and with few exceptions have had no difficulty in getting my fee, and apart from this firm in question, I understand my neighbouring professional confrères charge the same amount.

Of course I can quite understand that in the country, and in perhaps South and East London one would have difficulty in getting 10/6 a week for infirmary treatment of a cat, but equally their rent, rates, and taxes would be much lower, and I question very much if even in these places named qualified men would be found content to work at this scale of fees.—Yours truly,

HENRY J. R. POPE.

Kensington.

THE HOLIDAY DIFFICULTY.

Sir,

Referring to "Midlands" letter re exchange of practices, I have often thought this to be a very good idea. A change they say is as good as a rest, and I think you would find the weekly column suggested by "Midland" would be appreciated by many.—Yours faithfully,

BERTRAND SECKER, M.R.C.V.S.

Malvern Link. July 25.

Sore Throat

Broken Knees

Capped Hock

Cracked Heels

Sprains, &c.

THERMOFUGE

Is a compound of aluminium silicate, glycerin, boric acid, menthol, thymol, oil of eucalyptus, and ammonium iodide, forming a convenient and efficient anti-phlogistic application superior to poultices, fomentations, etc.

THERMOFUGE

Does not require the repeated changes which poultices necessitate and, unlike them, it does not afford a medium for the growth of disease germs.

THERMOFUGE

Reduces swelling and capillary congestion, allays pain, soreness and throbbing, and has an alterative effect upon inflamed glands. It softens indurated tissues, reduces tense tumefactions, and restores tone to strained tendons.

THERMOFUGE

Is a thick paste which is spread over the affected area (or applied on linen) and covered with oiled silk retained in position by a bandage.

Supplied in Tins of $\frac{1}{4}$, $\frac{1}{2}$, 1, 5 and 10 pounds.

Practices for Disposal

DEATH VACANCY. An opportunity of securing an old established country practice has occurred on account of death of principal. Situate in Eastern Counties. Represented as returning considerably over £400 p.a. Good contracts returning £160. Good house and premises at £45 p.a. Hunting in immediate vicinity. Further particulars and introduction only to would-be bona-fide purchasers.

15 MILES OF LONDON. A good-class mixed practice represented as returning about £650 p.a. is for immediate disposal. Capable of considerable increase. Nice and convenient house consisting of 10 rooms. Good stabling, coach-house and dog kennels. Strictest investigation courted. Good introduction will be given. Satisfactory reason for relinquishing. Further particulars on application.

DEATH VACANCY. An old established practice in a London Suburb is for immediate disposal, represented as returning £150. This amount, it is stated, can be easily increased by an energetic Practitioner. Price asked is £100 to include drugs, instruments, kennels etc. Inclusive rental of premises £1 2s. 6d. Further particulars and introduction on application

SALOP.—We have just placed in our hands for disposal a well-established Practice represented as returning last year £375. County Council appointments. Good reasons for selling. To an immediate purchaser Vendor will accept an offer of about £250 to include Surgery fittings, drugs, instruments, etc.

Orders for single copies by post, or short subscription (4 weeks (1/2, etc.), should reach this office by first post on FRIDAY MORNING.

The Record is posted to Subscribers on Friday, usually in time for the 5 p.m. collection. The normal issue consists of 16 pages of literary matter but this is varied to 20 or to 12, as may be required.

PRACTICES FOR DISPOSAL

SOUTH EAST COAST. Receipts 1910 £415. Good house, kennels, etc. Very well fitted surgery. Rent £40. Premium £450 and valuation.

SOUTH OF ENGLAND. In present hands 24 years. Receipts last two years average £835 including appointments £70. Convenient house, rent £21, larger house available if preferred. The practice has been worked principally by an assistant who would remain if desired. Premium only £800.

SOUTH COAST PARTNER WANTED. Receipts about £800 per ann. Good house available at moderate rent.

YORKS. Practice principally horse and cattle. Books 1910 show £575. Large convenient house with model stables for seven horses. Well fitted surgery. Rent £75. Practice very compact and easily worked. Premium £375.

NEAR LONDON. Present hands 9 years. Small house rent £30, the practice is principally canine and is easily worked. The returns are stated to be about £400 per ann. Premium one year's purchase.

KENT. High-class mixed practice, returning about £650 per ann. Good premises to be let on lease would be sold. Premium £600.

YORKS. Premium £250. Receipts 1910, £330. Rent £40. Stables and yard almost clear rent. Good agricultural and breeding district. Present hands nearly 20 years. Good house.

LONDON. Thoroughly sound practice, established over 100 years. Receipts about £1200 p.a. Fine house and thoroughly convenient premises. Rent £90. Practice is principally horse. Receipts increasing. Premium one year's purchase.

SOUTH COAST. Old-established Practice for Sale, returning about £550 per annum. Present hands five years. Convenient house, rent moderate. Premium £500.

LONDON. Present hands 30 years. Vendor retiring. Mixed practice. Rent £75. Receipts average £1078. Premium one year's purchase. Strongly recommended.

SEASIDE. Partner Wanted in old-established Practice capable of great increase. Receipts approximate £700. Working expenses low. Good house, rent £60. Premium for half-share £350.

SOUTH OF ENGLAND. Receipts average £650. In present hands 13 years. Usual fees. Good house, three stalled stable, four loose boxes, kennels, cat house, etc. Rent £85. Delightful residential locality. Vendor is well-known to us. Premium £750.

SCOTLAND. General mixed practice returning nearly £700 per annum. Contracts and appointments produce £250 per annum. Practically no night work. Established 30 years, 17 years in present hands. Good house, property of vendor. Rent £60. Premium one year's purchase.

H. J. DAWES, Hon. Sec.

Manager Wanted

FOR veterinary practice, large town, India. Salary £500 a year and house rent free, with option to purchase practice. Reply, stating qualifications, age and experience, to Bramall & White, Solicitors, 23 Leadenhall Street, E.C.

Class C Student

WISHES to spend a month or 6 weeks with a country practitioner during August and September. Willing to render his services in return for keep and railway fare. Address, J. Share-Jones, Liverpool University.

Class D Student

DESIRES to see practice until the end of September, has been up for the final and has seen practice. Address, Eason & Son, Ltd., Dublin.

As Locum or Assistant

FINAL year student (29) offers services as above, extensive experience as locum, mixed and dog. Ride and drive, disengaged after August 18th. Address, S. Woods, c/o M. Bray, M.R.C.V.S., Docking, King's Lynn, Norfolk.

Partner Wanted

IN extensive, old established horse and dog practice on the South Coast. Good contracts, average returns £650 per annum, with room for considerable increase. Address, 1081 V.R., 20 Fulham Road, London, S.W.

Unqualified Assistantship Required

BY young unqualified man, lately assisting in a veterinary practice, town and country. Good horseman and not afraid of work, age 21. Well up in all veterinary work. Moderate salary required. Address 1082 V.R. 20 Fulham Road, London, S.W.

As Assistant or Manager

M.R.C.V.S., married, requires permanency as assistant, or to manage branch. First-class all round experience: highest references: sober not afraid of work. Address, 1085 V.R., 20 Fulham Road, London, S.W.

Mallein and Tuberculin

MEMBERS of the Profession may obtain Mallein and Tuberculin on application to the Principal, Royal Veterinary College, Camden Town N.W., on the following terms: in bottles, 6d. per dose. Minimum quantity supplied, two doses. In hermetically sealed tubes, containing one dose each (specially suitable for use abroad) 1s. per dose.

G. H. PICKWELL, M.R.C.V.S.

LOCUM:

73 Victoria Mansions,
South Lambeth Road, S.W.

HUGH R. SINGLETON, M.R.C.V.S.

LOCUM TENENS.

Rosenheim,
Boscombe Park, Bournemouth.

Practice for Disposal

SCOTLAND. Death vacancy. General mixed practice is for immediate disposal, with shoeing forge. Returns £650 per ann. Good introduction will be given. Most suitable for a young practitioner with small capital. Reasonable terms can be arranged. Address, 1083 V.R. 20 Fulham Road, London, S.W.

Wanted

GENUINE country practice, unopposed, Yorks. or Northern Counties preferred. Small capital at command. Take over early date. Give full particulars. Bookings. Rent. Lowest price. Address, 1084 V.R., 20 Fulham Road, London, S.W.

Assistant Wanted

IN London horse and dog practice. Apply, H. H. Whitlamsmith, 1 Shardeloes Road, New Cross, S.E.

Open for Engagement

M.R.C.V.S., well up in town and country practice, excellent credentials, open for engagement any kind. Good operator. Locum, 79 Millbrook Road, Barington Road, Brixton, London.

To Veterinary Surgeons

CLASS D student desires situation; has seen practice. Services for board and expenses. Address, "Vet. Student," 11 Warrington Place, Dublin.

Locum Tenens

ADVERTISER would act as above, several years experience in town and country practice; good horseman, reliable references. Address: W. Cureton, Upton, near Birkenhead.

All communications respecting advertisements should be addressed to

H. & W. BROWN, 20 Fulham Road, London, S.W.

Tracheotomy Tubes

MISS JONES, successor to F. B. Jones, M.R.C.V.S., still continues to supply the Special Tracheotomy Tubes patented by her late father. Special terms to Veterinary Surgeons. Address, 86 Kimberley Road, Leicester.

To Veterinary Surgeons

CLASS D student desires position as assistant till 1st October. Services for board. Has seen practice. Address, 1086 V.R., 20 Fulham Road, London, S.W.

Locum Tenens

PRACTICAL qualified man wants engagement as above. Abstainer, good reference. For terms and particulars apply 1088 V.R., 20 Fulham Road, S.W.

Practice Wanted

WANTED, within 100 miles of Manchester or Liverpool, genuine established practice or good nucleus. Immediate settlement. Confidence observed. Address, 1108 V.R., 20 Fulham Road, London, S.W.

For Immediate Disposal

M.R.C.V.S., about to take appointment wishes to sell country practice, in good district, Scotland. C.C. appointment. Doing fully £300. Small price for quick sale. Address, 1087 V.R., 20 Fulham Rd, London, S.W.

Wanted

QUALIFIED assistant for suburban practice, state age, height, references and salary required, live out. Address, 1089 V.R., 20 Fulham Road, London, S.W.

To See Practice.

CLASS B student, farmer's son, wishes to see practice. Services for board. H. Chown, Blaygroves Farm, Mapledurham, nr. Reading.

Locum Wanted

FOR a week in a country practice, from August 12th to August 21st. Reply, stating terms and references, and age, to H. Bibbey, Winsford, Cheshire.

Locum Tenens

SON and Brother of V.S. is open to engagement as locum until October, when returning to college. Highest references from well known practitioners. Address, 2507 V.R., 20 Fulham Road, London, S.W.

Wanted

PARTNER with view to succession, in good mixed practice, returning about £500, room for considerable increase, half share £250 clear. Address, 5073 V.R., 20 Fulham Road, London, S.W.

Assistant Wanted

FOR London cart horse practice, recently qualified preferred; steady, sign bond. Apply, with full particulars, live out. Address, 5507 V.R., 20 Fulham Road, London, S.W.

Improver Wanted

FOR London cart horse practice, steady, board and remuneration for services. Apply, with full particulars. Address, 7507 V.R., 20 Fulham Rd, London, S.W.

Wanted

IN a mixed practice, Home counties, assistant for about a month. Class D student not objected to if practical. Write &c., experience, salary, references, and when disengaged to 9507 V.R., 20 Fulham Road, S.W.

To Veterinary Surgeons

LOCUM, assistant, branch manager, veterinary surgeon desires permanency, sporting, hunting, country practice. Experienced, reliable, practical, hard worker, castrate standing, good obstetrician, 34, single. Excellent references, interview. Address, 5074 V.R. 20 Fulham Road, London, S.W.

For Disposal

DEATH vacancy, Staffordshire, horse and canine practice, situated in centre of town, receipts £250 per ann., could be greatly increased. Good house, and kennels; working expenses small. Good introduction. Reasonable to immediate purchaser. Address, 3075 V.R. 20 Fulham Road, London, S.W.

For Immediate Disposal

YORKS, North Riding. Wanted, reasonable offer. Receipts over £300, good house to go with practice. Rent £12. Good agricultural and breeding district. Present owner 27 years; no opposition; C.C. appointment; introduction given. Address, 5307 V.R., 20 Fulham Road, London, S.W.

For Disposal

GENUINE old established town practice and shoeing business in Lancashire. Good premises, with every convenience for doing a large and profitable trade, carried on successfully for many years by owner, who is retiring. Address, 4042 V.R., 20 Fulham Road, S.W.

Wanted

M.R.C.V.S. seeks permanent situation in good class practice. Total abstainer: excellent references: well up in town and country work: good operator and horseman. Southern counties preferred. Address, 4072 V.R., 20 Fulham Road, London, S.W.

The Glasgow Veterinary College,

INCORPORATED.

Principal: JAMES MCCALL, F.R.C.V.S.

Session, 1911-1912.

This College is under the management of a representative Board of Governors and is recognised as a Central Institution under the Education (Scotland) Act, 1908. A complete course of instruction is given in the subjects of examination for the Diploma of the Royal College of Veterinary Surgeons, and the field for clinical observation is unsurpassed. The equipment of the College is being extended and modernised. Students are eligible for bursaries granted by Secondary Education Committees of the Counties and certain Burghs of Scotland.

The Matriculation Examination conducted by the Educational Institute of Scotland for intending Students will be held on 6th, 7th, and 8th July, and 7th, 8th, and 9th September.

Next Session commences on Wednesday, 27th Sep. 1911. Further particulars may be had on application to the Principal, or Alexander Russel, 54 West Nile Street, Glasgow, Secretary.

Saloform Pessaries.

The New Uterine Antiseptic

Highly recommended by many eminent
Veterinary Surgeons.

PRICES: Ordinary Strength, White.

4/6 per doz. 48/- per gross.

Extra Strong, Yellow.

6/6 per doz. 72/- per gross.

Sole Proprietors—

HARKNESS, BEAUMONT & CO.,

Wholesale Chemists,

EDINBURGH.

Veterinary Surgeons have for long keenly felt the want of something which could be used with good results as a Uterine Antiseptic and which at the same time could be quickly and easily administered. After many trials, and with the kind co-operation of some able Veterinary Surgeons of great experience in parturition cases, we have succeeded in producing

a Pessary made with a **non-oily base** which does its work efficiently and at the same time is non-irritant—in fact, soothing in its effect. They are of great use in parturition in cows or mares; and if administered immediately after parturition they will keep the Uterus clean and healthy, and prevent the after-birth becoming foul.

Veterinary Surgeons in various parts have highly recommended them, and there is an increasing demand for both kinds.

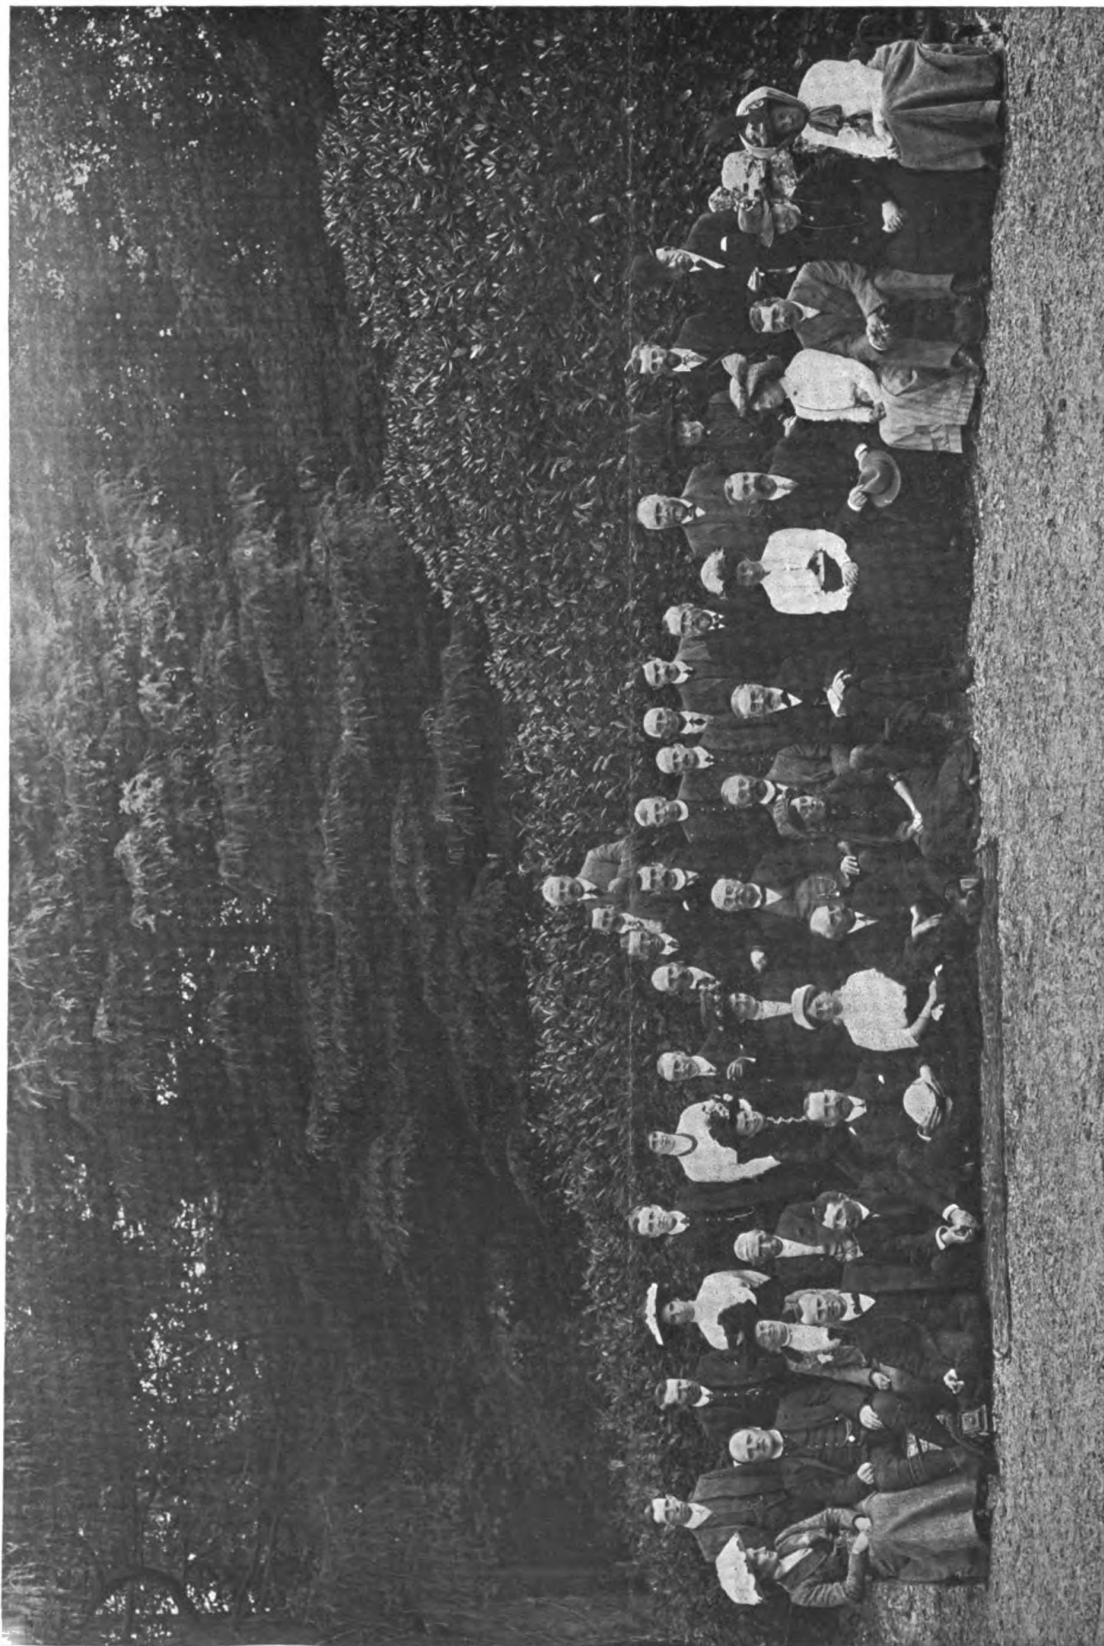

Customers are requested when ordering to state which kind they prefer.

A RECENT UNSOLICITED TESTIMONIAL.

AINSWORTH WILSON, ESQ., F.R.C.V.S.,
writes:—

"I have used the Saloform Pessaries supplied by Messrs. Harkness, Beaumont & Co., of Edinburgh, with good results in various diseases of the genital organs, both in mares and cows, more especially after parturition. They are particularly useful in retention of the afterbirth, with septic complications. It is often impossible to attend more than once a day to irrigate the uterus; in such cases it is good practice to leave one or two of the "extra strong" pessaries *in situ*. I have found them an excellent substitute for Iodoform and other well known non-irritating antiseptics. I feel justified in recommending them to the profession.

Witham, Essex."

THE VETERINARY RECORD

A Weekly Journal for the Profession.

EDITED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1204.

AUGUST 5, 1911.

VOL. XXIV.

COUNTRY PRACTICE.

In a recent Presidential address, the opinion was expressed that veterinary surgeons would do well to give more attention to pig-spaying. There is much truth in this for some districts, and for none more than the Eastern counties, to which the speaker—Mr. Heatley, of Woodbridge—especially referred. Taking country practice as a whole, it may well be asked whether practitioners are well-advised in so frequently neglecting the minor surgery of the farm, and especially the castration of ruminants and pigs.

These operations are chiefly in the hands of unqualified men, many of whom, by long practice, become exceedingly dexterous in their performance. A veterinary surgeon could more easily attain an equal facility in manipulation; and every one contemplating settling in country practice would do well to first become adept in this particular department of it. Whether he may elect to become one of the regular castrators of his district will depend upon circumstances. There are practices in which this work may very well be refused, but there are others in which it may become a very valuable addition to the income.

Castration is unpleasant, monotonous, and poorly-paid work, and these three reasons probably explain by so many veterinary surgeons refuse it; but there are many districts in which it is both directly and indirectly advantageous to the practitioner. Unremunerative as it is from one point of view, the direct advantage of including it in the regular day's work is often relatively very great. The indirect advantage is—that the unqualified castrator is very often also more or less of an unqualified general practitioner, and, if superior to the veterinary surgeon in one or two operations, may be held to equal him in other respects. Obviously these men are less dangerous opponents to a veterinary surgeon who can rival them in their own specialty.

There are many country districts capable of yielding a fair income to a veterinarian who, in Mr. Heatley's words, is "able to take on any work that comes along," but which will hardly yield a living to one of less all-round capacity. That was true even before the advent of motor traction, and its truth applies much more forcibly to-day. A working country practice has its disadvantages, and the minor surgery of the farm is certainly not one of its most pleasant features. But it is a branch of surgery with which every aspirant to country practice should thoroughly fit himself to deal.

CONTUSION "CAPPED ELBOW."

Capped elbow is perhaps more common amongst Army horses than in any other collection of equines.

Whatever opinion may be held as to the cause of capped elbow amongst privately owned animals, there is no doubt that the trouble in the service is due to insufficient bedding. The present system by which a regiment forages its horses takes the form of a "running account." The different varieties of forage have their separate values definitely allotted to them, and commanding officers draw those amounts of each which seem best suited to the work and condition of their animals at the moment. There naturally arises a tendency to economise in the matter of bedding in order to utilise the money in the purchase of foodstuffs, of which the utility is more immediately apparent. Added to this is the fact that in the South African command, whence the present observations on capped elbow have been drawn, the bedding consists of aromatic veldt grass which is greedily eaten by the majority of horses. Hence it is that at early morning stables one finds many horses with practically a bare floor. Yet another factor in the production of capped elbow in the service is the fondness of the soldier for placing the bedding far back in the stall. The reason given is that, when so placed, it cannot be eaten by the horses, and this would pass could it at the same time be made apparent why the hind quarters alone are considered worthy of protection from the hard floor. In the examination room one would of course promptly deal with the problem by saying that the soiled bedding from the previous night should be placed forward in the stall, and any fresh supplies behind, but unfortunately one has seldom in this rugged world the pleasure of dealing with such an enlightened intelligence as that of an examiner in hygiene.

The fact remains that "contusion capped elbow" figures largely as a cause of non-effectiveness in the veterinary officer's monthly returns. Shoeing as a possible cause has been eliminated by observing that horses shod with tips are equally liable to elbow bruising. It is almost superfluous to remark that "capped elbow" is due to injury to, and consequent inflammation of, the subcutaneous bursa at the point of the elbow.

The following notes on treatment have been taken from a series of twenty cases dealt with during the past six months at this station. The cases presented every degree of the disease from a simple enlargement of a subacute nature to an enormous swelling from which inflammation and oedema radiated to the knee and involved the axilla and the breast.

These latter had become infected from abrasions of the elbow. The routine treatment in each case was essentially the same, only slight variations being made where specially indicated.

Some cases were cast, the others operated upon standing. The hair was clipped over the whole extent of the swelling and the surface painted with Tinct. iodi. A solution of Novocain was injected at several points around the base of the tumour and sufficient time allowed for anaesthesia to be complete. A Syme's abscess knife guarded by the fingers from entering too deeply was inserted at the North pole, so to speak, and a single powerful vertical incision drawn right through to the South pole. The fluid contents thus liberated varied from blood stained serum to thick pus, according to the nature of the lesion; but it is worthy of note that even in the case of the most solid-seeming enlargement the fluid was considerable. The flaps were then held apart by an assistant, and all loose shreds, necrotic material, etc., dissected away. The cavity was washed out thoroughly, dried as far as possible, and a pledget of towsoaked in pure Tinct. iodi. inserted, over which the flaps were drawn together by a few loose stitches. Bleeding, which was in no case serious, was ignored except so far as to remove traces of it, after cessation, from below the wound, and to smear the limb with vaseline for protection from subsequent discharges. In 24 hours the stitches and pledget were removed and the cold hose pipe turned on to the cavity for half an hour. A fresh coat of Tinct. iodi. and a plug of tow completed the dressing. The cases were kept throughout the treatment on pillar chains.

The cold hosing and subsequent dressing with Tinct. of iodi. were carried out twice daily for a week, after which some cheaper dressing was substituted for the iodine, the cold hose being continued.

In every case the animals were discharged to duty within the month, healing being practically complete, and little or no trace of the previous enlargement being visible.

There is of course nothing new about this treatment, but in view of the many different ideas that obtain as to dealing with these cases and the frequent temerity as to use of the knife, it would seem possible that a record of this kind, adducing indisputable evidence of the safety and effectual nature of radical operation, might be useful.

The only instance of capped elbow coming under my notice lately which could not be traced to bruising from the stable floor is worthy of mention.

The animal is a small well-bred polo pony, the property of an officer in the 6th Dragoon Guards. Although kept in a well bedded loose-box and most carefully shod it was constantly troubled with a capped elbow complicated by abrasions. The cause, at first obscure, was eventually indisputably traced to the toe of the rider's boot and the stirrup iron, which frequently struck the pony's elbow during the game, renewing the abrasions and repeating the bruising. A broad felt pad attached to the stirrup iron stopped further injury.

WAKEFIELD RAINEY, Capt. A.V.C.
Bloemfontein, S.A.

A LIVING FREAK.

Freaks of nature are not at all uncommon, but it is seldom these freaks live, or are allowed to live, any length of time.

The photograph which I am enclosing is that of a cross-bred, three-year-old Africander heifer, with six legs, the extra pair of legs being attached by fibrous tissue to the lower third of the neck.

These extra pair, which by the way are fore legs, are well formed up to the carpus, but the olecranon process of the ulna in each leg, is greatly enlarged.

The humeri are fairly well formed, but are joined together by tissue. Both scapulæ are malformed and are attached by tissue to the cervical vertebrae in the lower third of the neck.

The heifer, I may add, is in good health, was bred in the Alexandria district, and is to be kept for breeding purposes, although as yet she has not had a calf.

J. NICOL, M.R.C.V.S., Govt. V.S.
Grahamstown, C.C.

AN UNUSUAL FŒTAL PRESENTATION.

We were called to attend a mare who was in difficulty with her foaling. On our arrival we found the mare had foaled unaided, but with the following strange presentation. Head protruding through the anus, and the forelegs through the vulva, and with this presentation she had delivered the foal (dead).

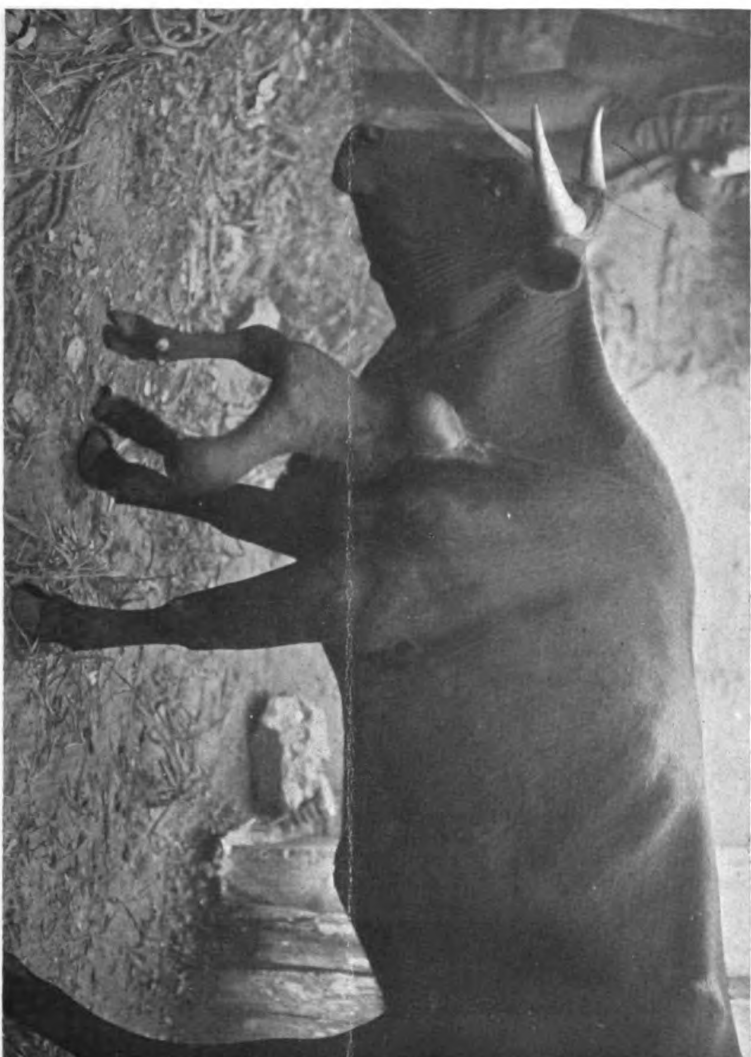

Examination of the parts revealed a rupture of the posterior portion of the rectum extending for about six inches, rupture of the anus and spinetters, together with complete obliteration of the septa between the rectum and anus and the vagina and vulva, with severe laceration of the vaginal walls and adjacent structures. Fæces were already present in the uterus, the visible portions of which were intensely inflamed.

The case being considered hopeless the mare was slaughtered, and the accompanying photo was taken.

Later on in the season we were called to another mare during her foaling, and on arrival found an exactly similar presentation.

In this case the foal was alive and little difficulty was found in returning the head through the ruptured membranes, and bringing it forward in its normal position; the foal was then "drawn" without any further trouble. Manual exploration revealed a rupture through the septum about nine inches long. The mare was walked to the infirmary (3 miles), the foal being conveyed in a cart. On arrival the anus was cleansed, the womb irrigated, and the ruptured portion drawn together with a continuous suture, a physic ball also being administered. After treatment consisted of cleansing the rectum and vagina twice daily with a weak solution of chinosol and giving a sloppy diet. In six days the suture was removed, the opening being completely closed, and the mare turned out.

"ERIN."

SUPERNUMERARY FORE LEGS,

Note by J. Nicol, Govt. V.S., Grahamstown, Cape Colony (p. 85).

MAL-PRESENTATION WITH RUPTURE OF
RECTUM AND VAGINA.

ABSTRACTS FROM FOREIGN JOURNALS.

THE TREATMENT OF PYOMETRITIS IN THE COW.

Messerle (*Schweizer Archiv.*) discusses this condition. The most common causes of bovine pyometritis (apart from uterine tuberculosis) are acute metritis after parturition or abortion, retention of the placenta, and death of the fetus six to twelve weeks after conception. In the latter case the fetus may be expelled, surrounded by its envelopes, or may remain in the womb and there undergo maceration. In the latter event symptoms of acute metritis are rarely observed.

The first manifestations of pyo-metritis are often but slightly apparent; and the affection may exist for rather a considerable time before attention is drawn to it. Very often the affected animals are thought to be pregnant, and valuable time is thus lost.

The affected cows do not come into season, and they present a purulent vaginal discharge of variable consistence. Sometimes this is constant, sometimes it is only observed at intervals. Direct exploration reveals that the neck of the uterus is sensibly more dilated than in a normal uterus. Rectal exploration shows that the uterus is more or less augmented in volume, and that the uterine horns are asymmetrical and contain liquid in which it is impossible to discover a body of firm consistence. The uterine walls are more tense than in a pregnant uterus, and the augmentation of volume especially involves the body of the uterus in pyometritis, whereas in pregnancy it especially involves one or both horns.

Spontaneous recovery may occur in pyo-metritis, and turning the cows out to grass appears to favour it. The author, however, employs the following treatment.

After having thoroughly disinfected the lips of the vulva, he passes the first finger of his right hand into the neck of the uterus; and then, by means of corkscrew movements, he successively introduces the middle finger and third finger. As soon as the uterine neck is thus dilated, the practitioner passes a tube of caoutchouc of from $\frac{1}{2}$ inch to 3-5th inch in diameter into the uterus. This tube should be soft and elastic; tubes of hard material, being able to injure the uterine mucous membrane, should be rigorously excluded from use.

As soon as the tube arrives in the uterus it often permits the escape of a purulent discharge, which is sometimes very abundant, and may amount to ten or twelve litres (approximately $17\frac{1}{2}$ to 21 pints). As soon as this purulent discharge is arrested, the practitioner injects ten litres ($17\frac{1}{2}$ pints) of a 0.5 per cent. solution of silver nitrate, which he allows to remain in the uterus for a few minutes, and then permits to flow away. Immediately afterwards he passes the tube as far as possible into the uterus, and maintains it in that position by holding it with his left hand at the vulva. He then introduces his right hand into the rectum, and energetically massages first the uterine horns and afterwards

the body of the uterus, proceeding always from before backwards. During this procedure he slowly withdraws the tube, and is thus enabled to completely empty the uterus, which could not be done by a simple irrigation.

It is important to note that under the influence of this manipulation the uterus undergoes considerable contraction, especially when it contains a large quantity of secretion. It is not rare to see the volume of the organ diminish in the proportion of two-thirds.

After the massage, the author examines the ovaries and treats them if necessary; and finally, he gives the animals an infusion of savin for a period of two days.

In the year 1907 the author treated 26 cows in this manner, and obtained 24 recoveries after a single application of the treatment. He considers animals which do not recover after a single application of treatment as incurable. He considers an animal cured if she comes into season again, which event generally occurs from 8 to 14 days after treatment.

He recommends that the animal should not be covered at the first coming into season.

As regards the question of whether cows which have undergone this treatment are likely to conceive again, the author thinks that the chances are more favourable when the disease has not been of long standing. The prognosis is favourable in this direction, if the duration of the affection has not exceeded nine months.—(*Annales de Méd. Vét.*)

Royal College of Veterinary Surgeons.

EXAMINATIONS IN DUBLIN.

At the meeting of the Board of Examiners held in Dublin on July 14th, 20th, 21st, 22nd, and 24th, the following gentlemen passed their Final Examination and were admitted Members of the Royal College of Veterinary Surgeons:

Mr. P. J. MacCormack	Mr. T. M. Doyle
M. Cunningham	P. D. English
M. J. Reidy	T. F. O'Brien
J. M. Crowe	T. Le B. Revington
P. F. Dolan	J. Smith
H. W. Carbury	N. D. Vakil

The following passed their Third Examination:—

Mr. M. Brett	Mr. T. McD. Kelly *
M. P. Glynn *	T. O'Leary
J. J. Cosgrove *	J. Quinlan *
H. E. Irwin	F. B. Sneyd
J. R. Jackson	R. C. Wheeler

The following passed their Second Examination:

Mr. A. E. Brandon	Mr. J. P. McNally *
E. S. M. Morgan	J. J. Mills
T. G. Browne *	J. J. Pomeroy
T. D. Condell	A. D. Preston
J. R. Ellison	T. Reddin
D. C. Green *	C. M. Stewart
M. P. Hatch	M. Toomey
J. J. Hegarty	

The following passed their First Examination :

Mr. I. C. Blake	Mr. H. Jewell †
J. O'Carroll	M. J. Killelea
W. A. I. Buchanan	W. E. Little
T. A. Connolly	P. J. Mulcair
F. Daly	O. D. Neary *
G. J. Delaney	T. F. O'Connor
H. Dolan	W. P. Power *
R. Hans	M. J. Ryan
C. P. Fisher *	G. K. Shaw
P. J. Hayes	

Marked thus * passed with Second Class Honours.

SOUTHERN COUNTIES VETERINARY SOCIETY

A meeting was held at the George Hotel, Portsmouth, on Thursday, July 13th, when the President, Mr. Wm. Hunting, F.R.C.V.S., took the chair, and the others who signed the attendance book were : Messrs. A. H. Archer, C. W. W. Brown, Southsea ; W. A. DellaGana, Southampton ; G. H. Livesey, Hove ; A. Maynard, Bournemouth ; C. Pack, Lymington ; R. Roberts, Tunbridge Wells ; W. K. Stuart, Hove ; H. Smith, J. Alex. Todd, Worthing ; J. G. Tait, Christchurch, together with Capt. Duncan Macdonald, A.V.C.

On the proposition of Mr. Livesey, seconded by Mr. Roberts, the minutes of the last meeting as published in *The Veterinary Record* were taken as read and confirmed.

The HON. SEC. reported the receipt of letters or telegrams expressing regret at inability to attend from Professors Hobday and Wooldridge ; Messrs. J. T. Angwin, E. Whitley Baker, W. Burt, junr., G. W. Bloxsome, W. Coveney, Chas. J. Callow, J. B. Dier, J. T. Firr, C. W. Howard, H. H. Jeffries, J. C. Munby, J. B. Martin, C. Roberts, C. H. Spurgeon, S. H. Slocock, R. A. Thrale, F. T. Walder, A. C. Wild, D. Wyllie, A. Whicher, and R. F. Wall.

The HON. SEC. also read a letter from Mr. Percy Simpson, of Maidenhead, tendering the resignation of his father as a member of the Society.

Mr. ROBERTS remarked that he was sure they would all deeply regret the resignation of such an old and valued member as Mr. Simpson, senr., but they could not do other than accept it. They were all sensible of the great grief into which the family had been plunged, and they could only sympathise with them in their trouble, and accept the resignation of Mr. Simpson with regret. He proposed that this be done.

Mr. DELLA GANA seconded, and this was at once agreed to.

Mr. J. G. TAIT, of Christchurch, who had been formally proposed and seconded at the last meeting by Mr. E. Whitley Baker, on behalf of Prof. Hobday and Mr. Maynard respectively, was formally elected a member of the Society.

The selection of a place for the holding of the next meeting then engaged attention, and

Mr. DELLA GANA suggested that they might try and hold a meeting at Aldershot. They had not held a meeting there yet, and he thought it would make a very good centre.

Mr. ROBERTS seconded this, and it was eventually put and carried, it being understood that in the event of its being found impossible to arrange a meeting at Aldershot, the next meeting at the end of September should be held at Brighton. The Hon. Sec. was also requested to try and arrange for a visit to the Army Veterinary School, and an inspection of the X-rays apparatus.

PRESIDENTIAL ADDRESS.

WILLIAM HUNTING, F.R.C.V.S.

Gentlemen,—My first duty is to thank you for the honour you have conferred by electing me as your President for the coming year. I am just a little doubtful whether it would not have been better to have chosen a man more in the centre of your district than one from London. But I shall endeavour, with the assistance of Capt. Todd and the other officers and members of the Society, to maintain the success which has for some years marked the progress of the Southern Counties Veterinary Society.

We have a tolerably full programme to-day, and I ought not to waste your time with any presidential remarks, but I cannot refrain from just alluding to one or two matters which are interesting and important to our profession.

You know that as a Corporate Body we are in a bad financial position—expenditure exceeding income by about £400 a year. It is true we have a small capital sum that our forbears, by good management and economy, stored up for us. But this capital will only last a few years, and then we shall directly face bankruptcy. We must somehow increase our income, and our Council has endeavoured to provide a way by imposing an annual contribution from every member resident in the United Kingdom. Before they can enforce this an Act of Parliament must be obtained and a Veterinary Amendment Bill has been draughted for submission to Parliament. This Bill was at first overweighted by a number of clauses that provoked powerful opposition. It has now been cut down merely to a Bill concerned with our own domestic affairs. If it became an Act the Council would have power to collect a guinea a year from each of us. It seems strange, although true, that we cannot get this Bill unopposed through Parliament, and still stranger that the opposition comes from members of our profession. The opposition is voiced by four or five members who claim that they represent a minority respectable in numbers. The claim is based upon some replies to a circular sent out years ago which have little or no bearing on the existing Bill. Whilst I quite fail to understand the actions of the opponents, I am willing to credit them with good motives, but I remember the old adage, that "much evil is done by honest men when misdirected."

There is one good argument for the Bill—that the Council want money badly and that no better way of getting it is apparent than the Bill. It seems an exhibition of strained economy to say that a charge of 5d. a week is less bearable for a veterinary practitioner than for a coal miner.

A question is asked—What will the Council do with the money? Surely the Council, our representative body, fairly elected, one-fourth every year, may be trusted to do what is right? If they did not the profession has a ready way of correcting them. We want money to ensure our progress, to protect our interests, and to increase our efficiency as workers for the public good.

Among the things for which money is required is the suppression of quackery. I do not mean that we should run a tilt against men who sell quack medicines, but we should attack wherever we meet these men using titles with intent to deceive the public. Not many quacks now use the term "veterinary surgeon," but every year sees some ingenious person inventing a word or title which implies or suggests that the public may accept him as a qualified doctor of animals. In the present state of our funds we cannot afford to prosecute, and remember, that if a case were taken to the House of Lords it might cost the College £1000.

As to the ordinary quackery which lives on the sale of drugs of unknown composition, we as a Corporate Body can do nothing except wonder at the gullibility of stockowners. We cannot counter it by lying advertisements, nor can we force sales of our own at markets, fairs, and shows, where gratuitous whiskey and soda assists the insidious tales of cure. We must wait until stock-owners recognise that every disease is not accompanied by an antidote in the shape of something in a bottle or a packet. We must wait until the public understand that medicine and surgery can only be honestly and successfully applied when the doctor has each case under his observation.

In the meantime we must go on making ourselves efficient, and the public will in time find that their interests are safer in the hands of qualified men than in those of commercial impostors.

Our calling is very much the same as others—it contains men good, bad and indifferent, but somehow I think it has one prominent failing—a want of *esprit de corps*. The soldier is willing to die for his flag. The miner will face starvation under the guidance of his union for what he considers his rights. Doctors, parsons, and lawyers feel a collective sentiment that binds them together for the protection of their interests. But only some 10 per cent. of veterinarians exhibit any care for their Body Corporate until their own personal interests are affected or threatened.

This aspersion does not apply to those who are members of such associations as this. In every district of the country we find local associations whose sole reason for existence is the desire to help each other, to further veterinary science, and to work in unison with the Corporate Body of which we form a part. At present we are separate bodies, and somewhat isolated, but it is good to remember that the independence of each has been a feature of our development—valuable because preserving some originality and promoting some healthy rivalry.

No one who reads a newspaper can have failed to notice the success which has attended lately the strongest organisations. The Insurance Bill now before Parliament looked like inflicting injury upon medical practitioners. It will not do so simply because the united profession guided by the British Medical Association has put its case powerfully before the Chancellor of the Exchequer and before the individual members of Parliament.

It is proposed to make a further effort for closer union in our profession. It is hoped to link up in one, all the veterinary associations so that any subject affecting us may be widely and immediately taken into consideration. This affiliation scheme hopes to produce union without any interference with independence. For years something had been attempted, but only this year have all our difficulties been surmounted. I venture to hope that the meeting at Carnarvon will be able to accept the scheme, and that next year will find it a working entity.

A Certificate or Diploma granted by an acknowledged College or teaching institution is not always proof of very special attainments, but it is evidence that its holder has had special facilities for learning, and it is widely accepted as ear-marking its holder as more desirable than the man with no credentials.

The higher veterinary degree of Fellowship, has, I think, been useful to us, not because the general public appreciate it as a mark of superiority, but because it has cultivated a spirit of emulation, and attracted many young men to continue their scientific reading and study after leaving College. I think the objects and the methods of the Fellowship have hardly kept up to the standard of modern requirements, and the Council of the R.C.V.S. is also of this opinion. They referred the

matter to a Committee which, after consideration, has reported.

The alterations suggested by the Committee are that the Fellowship Diploma should be continued, but so modified that it would be granted in two divisions and by two separate examinations—one for men who desire to practise clinical medicine and surgery—one for those who desire to specialise on State and Municipal medicine. This latter division is certainly so specialised as to be worthy of a new diploma showing special knowledge in chemistry, pathology, and epidemiology, with meat inspection and hygiene.

Such a diploma would ear-mark men specially fit for appointments which are constantly increasing. It would entail a course of post-graduate study—an inestimable thing for those able to enjoy it. Such a diploma would be evidence to State and Municipal authorities that its holder was a man they could trust with the special work required of their veterinary officials.

Speaking of special work in relation to animal life I am reminded of one branch of veterinary practice that has in the past been insufficiently followed up. I mean the ravages of parasites. Quite recently I read a lecture by a Professor of Agriculture on Farm Parasites. It was a most interesting lecture, but I was struck by the little mention of what had been done by veterinarians.

It occurred to me that practitioners ought to apply the knowledge they really possess, and cultivate still more their knowledge of a subject that is certainly and rapidly being recognised as of first importance.

It would be a pity if our men permitted this division of science to be appropriated by other professional men. Veterinary practitioners seem specially fitted to practically apply the discoveries made by biologists and entomologists in the world of parasites.

All these steps to acquire increased efficiency mean more work, more teaching, and more remuneration. They mean also more money. If our centre be poor we suffer from anaemia to the circumference, and I am brought back to the question with which I started. Let us get money for our Body Corporate, and every individual will reap a benefit. (Applause).

Mr. ROBERTS suggested that they could not do other than pass a very hearty vote of thanks to their President for the excellent address he had just given them, and which had contained such a fine review of the present position of the profession. It was a paper they could not discuss—they never did discuss the Presidential address—but at the same time they could not help appreciating it. Their President evidently realised the dangers with which their profession was beset, and also the good and benefit which might come to it if proper measures were taken for its advancement. Personally he was particularly pleased to hear Mr. Hunting's remarks respecting what he might call the politics of the profession, and he thought he had rendered them yeoman service in bringing the position before them in such a clear and lucid manner. He had very great pleasure in proposing that their best thanks be given Mr. Hunting for his Presidential address.

Mr. W. K. STUART had much pleasure in seconding this, and he hoped they would all read, mark, learn, and inwardly digest the address to which they had just listened.

The proposition was then put and carried by acclamation.

The PRESIDENT, in briefly acknowledging the compliment, said he had felt it was taking rather an unfair advantage of them to deal with the questions he had when he knew they would not be able to discuss them, but at the same time he felt it might be worth his while to express his own opinions even though he could not be controverted on the spot.

The discussion on the paper contributed by Mr. Bloxsome to the last meeting of the Society on "Some debatable points of unsoundness in horses" came next on the agenda, but in the unavoidable absence of Mr. Bloxsome,

Mr. SMITH proposed that they should postpone this discussion until the next meeting, when Mr. Bloxsome might be in a position to attend and defend his paper. Mr. Roberts seconded this, and the proposition having been agreed to

Mr. DELLA GANA offered to open the discussion on that occasion.

MILK FEVER.

By A. H. ARCHER, M.R.C.V.S., Southsea.

I make no apology for bringing this subject before this meeting, because, although the symptoms and general conditions attending it are so well known, and an efficient remedy is generally employed, yet no definite cause for the development of this disease is recognised by the veterinary profession. I regard it as somewhat humiliating, from a professional point of view, to be compelled to confess when asked the question as to the cause of milk fever (which very frequently happens to those who practise much among milch cows) that we are ignorant on this point, and I fully believe such an admission tends, in no small measure, to lower the status of the individual, and through him the veterinary profession as a whole, in the estimation of that particular querist and consequently of the public generally.

The object, then, in introducing this subject for discussion is that, if possible, a common agreement may be arrived at, as to what are the conditions or exciting causes that produce the affection known as milk fever. I sincerely trust that the matter will be thoroughly thrashed out by men who have had clinical experience of this disease, and that to these will be added the scientific theories regarding it.

I now proceed to state my own views as to the causes by which a typical case of that most common form, parturient apoplexy of the cow, is produced.

Parturient apoplexy is intimately associated with milk production, and especially that constituent of milk known as butter fat or cream, so that this natural, physiological function must be to a considerable extent instrumental in bringing about the disease, and I believe that a toxin developed during this process is one of the most important features in the causation of milk fever.

Secondly, certain breeds of cows are more frequently the subjects of parturient apoplexy than others, and certain strains of certain breeds suffer in this way to a greater extent than other strains, even of the same breeds, but it is in the deep cream-producing strains that the disease is specially liable to appear.

Thirdly, cattle of a certain age are much more likely to be attacked than others. Thus a young cow or heifer with the first calf seldom or never suffers in this way, with the second calf it is not common, although it does occasionally occur, but when it does so it is usually in an animal that has either attained a considerable age before becoming pregnant with the first calf or an unusual length of time has elapsed between the first and second calving; while the third and fourth calvings afford the most numerous cases of parturient apoplexy. Consequently one is led to infer that age, or rather maturity, has something to do with the production of the disease.

Fourthly, it is undoubtedly a fact that this disease is more prevalent in some districts, and on some soils, than others, quite independent of the breeds of cows kept on these soils or of the general management of the animals. I wish particularly to call attention to this, because it is a rather common practice to attribute the prevalence

or absence of parturient apoplexy in a herd solely to the way in which they are usually kept, or to some special manner of treating them during their breeding life, no consideration being given to the effect the food grown on the soil on which they live may have in producing the disease.

Of course I do not wish to imply that no care should be bestowed on the way animals, and especially where the disease is prevalent, should be treated during pregnancy or at the time of parturition, for undoubtedly neglect under such circumstances is often an important factor in developing the disease, but what I think is very important to note is that the disease does sometimes occur when every precaution has been taken, while in numerous instances where there appears to be gross carelessness, in the treatment of even animals apparently likely to become victims of this affection, no trouble in this respect happens. General or special treatment does not ward off the disease but only diminishes the likelihood of it developing.

Hereditary tendency is a matter which is disputed by some persons and ignored by others, but in my opinion it plays quite an important part in the production of parturient apoplexy.

The anatomical conditions, which are in existence in cows, in some degree so to explain the symptoms present in most cases. I refer to the conglomeration of small bloodvessels, known as the *rete nobile*, in the brain of cattle, also to the size of the rumen, and to the general distribution of the blood vessels in connection with the genital organs, and the mammary gland. These anatomical details are well known to all of you, but I merely ask you to bear them in mind when considering the causation of the disease.

The physiological conditions existent in connection with milk production and parturition, must, it seems to me, be regarded as the main feature in the causation of parturient apoplexy, and I propose dealing with these in detail and at some length. It is generally acknowledged that the capacity for milk production, or more strictly speaking cream production, in an average cow, attains its height with the third or fourth time of calving—usually the former.

The "fatty degeneration," to use a common phrase, although I do not think it is technically correct to style what is a natural healthy physiological process a "degeneration," which takes place in the process of milk formation, is not the only change of this description that occurs about the period of parturition, for it must be remembered that during pregnancy muscular tissue is developed in the uterine walls to assist in the expulsion of the fetus, and these muscular fibres are removed by a degenerative process which begins to take place almost immediately after the act of parturition is accomplished.

It is also almost certain that in animals in which "fatty deposit," that is the accumulation of fat in the tissues, has taken place during pregnancy, a certain amount of this deposited fat undergoes a degenerative change, thus there are three separate sources at which fatty change is especially in evidence about the time of parturition, and this "change" is at its greatest activity in an animal that has attained maturity, has received food during the latter stages of pregnancy which has a tendency to develop fat, or fat forming tissue, and also possesses a constitutional predisposition peculiarly liable to the "fatty degenerative" process.

The existence of disease in certain other organs, notably perhaps the liver and spleen, may also be an important factor in aggravating the degenerative process as well as rendering the system less able to withstand the effects produced by toxins, particularly those having a depressing influence, hence the probable reason why a very considerable number of fatal cases of par-

turient apoplexy are found on careful post-mortem examination to be affected by more or less chronic disease of one or more internal organs.

Any influences, therefore, which have the effect of suddenly causing excessive "fatty change" about the time of parturition within several weeks after calving has taken place, may bring on an attack of parturient apoplexy. I have known quite a number of what in every particular appear to be genuine cases of this disease, affecting cows at a time as long as four, five, or six weeks after giving birth to a calf.

Another important incident which occurs at the time of parturition, and which I fancy, although well known, is frequently lost sight of, is the sudden diversion of the blood stream from the uterus where it has been the source of nourishment to the fetus, to the other parts of the system of the cow, consequently there is a temporarily engorged condition of the circulatory vessels when these are in a more or less atonic condition from partial disuse, and thus less able to deal with the bulk of blood suddenly driven into them. A state of congestion is set up, especially in the small vessels, such as those of the brain, with resultant ill effects on the animal economy. This inertia or partial temporary paralysis of the blood vessels being materially increased by the presence in the blood itself of any toxin of a depressing character, and this is what I believe actually takes place in the production of a case of parturient apoplexy, the toxin being absorbed from the centres when degenerative change has been going on.

That toxins are developed or liberated during the process of "tissue change" is, I believe, undisputed, and the fact that in pure cases of parturient apoplexy these toxins become absorbed by the blood vessels and so exert their baneful influence on organs remote from the place where they are generated accounts for the early development and prominent feature of brain and spinal trouble in this disease.

The chemical phenomena in the causation of parturient apoplexy attains importance in that the toxin developed in tissue change possesses in these cases a depressant action on the nervous system generally, and is very marked in the "sympathetic" system, hence the causation of milk secretion in the early stage of the disease; and it is the consideration of this depressed condition of the nervous system, and through it of the circulatory system, that accounts for the rapid recovery from quite an acute attack, so that an animal which is in a comatose condition is often to all appearances well on the high road to complete recovery within from thirty minutes to four hours. This fact is a strong argument against some of the theories advanced as to the actual cause of this disease, such as the absorption of septic matter etc., because in those diseases recovery is always more or less protracted and restoration to health is dependant upon the elimination of the offending material from the system, or the neutralisation of the deleterious matter associated with it, which requires considerable time.

The influences of the dietetic and general management on the production of parturient apoplexy have already been alluded to, and little need be added except to impress it upon the mind that certain soils are certainly favourable to the production of food stuffs which if fed to cows result in a large amount of fatty tissue change, and that land on which a beast will fatten is not necessarily, although it may be, noted for its power of producing cream. Also any course of management, dietetic or other, which tends to lower the "tone" of a pregnant cow near the time of parturition, renders her a more susceptible subject for an attack of milk fever; therefore regular exercise is one simple agent which helps to ward off an attack.

These theories also explain why animals recover suddenly, and why the principles of the present curative

treatment are, when carefully carried out, so eminently successful.

The fact of this disease being an "apoplexy" and not a "fever" sufficiently explains why there is no rise of temperature in an *uncomplicated* case of parturient apoplexy.

It now remains to compare parturient apoplexy as met with in the cow to parturient diseases of a more or less similar character as they appear in other animals—the mare, sheep, sow and bitch and human female, and I at once proceed to say that in my opinion in none of those does the disease, appropriately designated "parturient apoplexy," at any rate in an uncomplicated state, occur in females other than the cows. I freely admit both that cases do occur in the cow, that while partaking in some respects of the character of parturient apoplexy, yet are not typical of this disease, and also that numerous cases are met with in other females about the time of parturition which simulate, in some particulars, a case of true parturient apoplexy.

The former of these are cases in which intense nervous excitement, as shown by champing the jaws, plunging about, wildly glaring eyes, etc., and in a milder degree frequent twitching and shaking of one or both hind limbs, but these symptoms I attribute to either some special condition of the great nerve trunks and nerve centres themselves, or their adjacent tissues, or to the presence in the blood stream of another poisonous element.

Those instances in females other than cows which in many or some respects present symptoms similar to those met with in typical parturient apoplexy, according to my belief, are cases in which there is present a certain amount of a toxin caused by fatty change or some kind of degeneration of a like character, yet the real or chief cause of the trouble is a form of septic poisoning, set up by the absorption, from the genital organs, of putrefactive organisms, which causes an elevation of temperature, thus giving rise to the old and common name milk fever.

Before concluding, I wish to direct attention to one sequel to parturient apoplexy which occasionally makes its appearance just when the crisis of an ordinary case has passed, I allude to that condition so well known to those of us who have had extensive experience in the treatment of milk fever, which results in more or less atrophy of the muscles of one or both hind limbs, and by rendering the patient incapable of rising, or preventing the full use of the limbs, make it advisable to destroy the animal as useless.

What the precise character of this secondary trouble is I have not so far been able to determine, and I trust the discussion on this paper will tend to some enlightenment on this subject. At present I am inclined to regard it as neuro-phlebitis, if I may coin such a word, caused by injury to the large nerve trunks, and through them impairing the circulation in the blood vessels of the hind quarters. The first appearance of this condition is a painful swelling in one limb, causing the patient to become restless, with accelerated breathing and impaired appetite. These symptoms usually increase in intensity until the animal, if allowed to live sufficiently long, becomes reduced almost to a skeleton when both limbs are affected; or if only one, she may be able to rise, but rarely acquires the proper use of the affected limb, so that it not infrequently happens that the development of this secondary trouble leads to a most disappointing termination to a case. Indeed, it is nearly always best for the owner and most merciful to the suffering animal to destroy her when well pronounced symptoms of this sort appear.

I hope that this paper will provoke a good discussion, and that some definite decision *re* the cause of milk fever may be arrived at.

DISCUSSION.

The PRESIDENT remarked that they had listened to an extremely suggestive paper. Perhaps the deepest impression the paper had made on himself was that he had really no business to be in the chair that afternoon, because milk fever was a disease which he knew nothing or very little about, and it only showed the futility of having a town man to preside over a discussion by country practitioners of a subject like this. This was a subject in which a theoretical knowledge of medicine did not help one very much, but even the most ignorant of them knew that whereas milk fever used to be a disease in which the great majority of cases had a fatal termination, five per cent. of deaths was now about as much as any one might expect. When he was a young man nearly all these cases died, but then they knew nothing of this injection of the udder. This injection of the udder and its speedy action certainly seemed to suggest that the primary mischief must be in the udder, but whether that was so or not they must admit that one of the most remarkable discoveries of recent years was made by Schmidt when he tried this theory of injection.

Mr. ROBERTS wished to thank Mr. Archer for the very excellent paper he had given them. He thought it showed that their friend had had a very great deal of practical knowledge of the subject, and that he must must studied it very closely to have arrived at the conclusions he had. This complaint had been theorised on for a great many years, and as far as the pathology of it went he did not know that they had advanced very much. Some twenty-five years ago, when he was down in Westmoreland, he had an opportunity of making quite a large number of post-mortem examinations and the most prominent feature he noticed was the condition of the brain and its membranes. Quite a large quantity of serum invariably escaped when the membranes were severed, and this he used to think was the cause of the brain pressure. At the same time he must confess he never saw any symptoms of true apoplexy, such as rupture of the blood vessels themselves. Another point he had noticed was the temperature. Mr. Archer had told them he had never seen a case of milk fever in which the temperature was not always sub-normal, and he thought that was what they generally saw; whenever there was any pressure on the brain down went the temperature. And the first symptom they began to note in the case of recovery was the temperature beginning to rise again. He also agreed with Mr. Archer that it was the rich milkers that were the most liable to get milk fever. With regard to the fatty degeneration and other changes that were said to take place in the tissues, he had for some time now discarded that idea, and the thing that made him do so was the tremendously rapid recovery that took place after the udder was inflated with oxygen gas. Of all the wonderful things he knew of with regard to the veterinary treatment of diseases in animals, there was nothing he thought so absolutely wonderful in its effect as this new treatment for milk fever. It was perfectly marvellous to see the changes which took place in the patients, even in so short a space as two or three hours.

Mr. PACK remarked that according to their agenda they were to discuss the treatment of milk fever and its relation to other parturition diseases. What they wanted to find out was what milk fever really was. He thought there was no doubt it was a toxin which commenced somewhere about the hind quarters, gradually pervading the whole system, but he did not think the brain itself suffered so much. He could not think that this pressure on the brain had so much to do with milk fever. For one thing the rapid recoveries that took place did not seem to suggest that the brain was so

affected by congestion as they used to think, and they must also remember that twenty-five years ago milk fever was invariably treated by copious bleeding, with the result that there was more likely to be anæmia than congestion. He quite agreed that the disease was not nearly so severe now as it was twenty-five years ago, and the time the disease took to develop now was far longer than it used to be. What the cause of this was he could not say, but perhaps the explanation was that the disease had been handed down from progeny to progeny until the animals had acquired a certain tolerance to the complaint. He quite agreed with what had been said as to there being a good deal of luck in the treatment.

Mr. H. SMITH desired to thank Mr. Archer for his interesting paper. He agreed with Mr. Pack about the disease having apparently to some extent worn off. It did not seem anything like so severe now as it was twenty-five years ago. They often heard of diseases wearing themselves out in the course of time, and he was inclined to think that possibly milk fever was one of them, although the treatment adopted of injecting into the udder was a very wonderful one. Lately, whenever he had been asked for a preventative of the disease he had advised keeping the udder full until the animals were well past the three days, and in nearly every dairy in which this had been tried they had no milk fever.

Mr. LIVESY remarked that this was a subject he knew very little about, but he could support Mr. Smith in one thing, and that was the desirability of keeping the udder full. Some time ago when he was down in Worcestershire an old farmer told him he had never had a case of milk fever, for the reason that he took good care the udders were never interfered with for three days after calving. His (the farmer's) experience had been that if the udders were kept tense there was practically no milk fever, and that experience was borne out by Schmidt's treatment. He had hoped Mr. Archer would have mentioned some of the other parturition diseases, and discussed the relations between milk fever and some of these, and particularly would he have liked to have heard something about eclampsia; also if the disease was due to toxins, why should the result of the toxin be seen early in the case of milk fever, and why it should be seen late in eclampsia. At the same time he must congratulate Mr. Archer on having given them a most interesting paper.

Mr. MAYNARD confessed that he did not know very much about this milk fever treatment at present, although he had seen a good deal of it down in Cornwall. His own idea was that by injecting into the udder they possibly stopped the formation of these fat cells at the time of parturition, and they consequently did not get them carried into the circulatory system. He might also mention that he had at times been obliged to use only an ordinary bicycle pump for injecting, although he always liked to use a proper oxygen pump.

Mr. ROBERTS said it appeared to him that the food very often had a good deal to do with it, because when the land was in a very poor state they did not have much milk fever, but directly they got the land into a rich state, and the animals began to thrive and give plenty of good rich milk, they had the fever.

Mr. TAIT, who was invited to contribute to the discussion, remarked that he had been greatly interested in the paper although he did not know that he could contribute much to the discussion. In Scotland, before this treatment by injecting into the udder came into vogue, their method of treatment was principally by stimulants, and he thought they had about fifty per cent. of recoveries. But he agreed with what one or two of the previous speakers had said, that there was very often a good deal of luck. Occasionally they would have a good

many recoveries, and then they would have a spell of fatalities.

Mr. DELLA GANA remarked that with regard to the cause of this disease he thought the experience pointed to a toxin, due most likely to some ultra microscopical organism, and it was very likely that the fat cells which had been referred to conveyed these organisms into the system. He also thought the therapeutical value of the new air treatment was due to the fact that these organisms perished in the oxygen.

Mr. A. H. ARCHER, in reply, said he hoped this would not be the last they would hear of this subject, because, as he had stated in his paper, he should very much like to get a definite decision as to what was the cause of the disease, especially in the interests of the younger members of the profession, who would then be in a better position to satisfy the owners of any animals they might be called in to treat. With regard to what had been said about keeping the udder tense, he was born on a farm which used to calve a great many dairy cows and they never had more than about three cases of parturient apoplexy in thirty years, despite the fact that they did nothing to prevent it, and they always used to milk them out after the calving. On the other hand, a brother-in-law of his who was only seven miles away, and who had the same breed of cows tried everything he could to prevent it, but used to have any number of cases. In his opinion the udder distension had nothing to do with the cause. He preferred to attribute it to the atonic condition of the circulatory system. With regard to Mr. Livesey's remarks respecting other parturient diseases, the reason he had not gone into that was that he was afraid it would make the paper too long, and further there was no other parturient disease that he was aware of absolutely identical with it. Eclampsia was in his opinion due to poorness of blood, and was absolutely different from parturient apoplexy, though there was a similarity between certain of the symptoms. Then as to this infiltration of the udder, he believed when Schmidt first started his injections he did not inflate the udder, but introduced iodide of potassium with a view probably of killing the microbes which he assumed to be present in the udder. Some time before this treatment was made public he himself had come to the conclusion that it was a form of poisoning similar to that of carbonic acid gas, because they always got the blood very dark in colour, but it never occurred to him to inject it into the udder, and he started with peroxide of hydrogen as being very safe. He thanked them for the attention and interest which they had given to his paper, and if it had the effect of leading to a further ventilation of the subject he would be only too pleased.

One or two specimens of interest were exhibited and commented upon.

Mr. LIVESEY proposed the customary compliment to the President for presiding, and this was seconded by Mr. Roberts, and carried by acclamation.

The PRESIDENT briefly acknowledged the compliment, but suggested that their thanks ought really to have been accorded to Mr. Archer for giving them such an interesting paper.

Mr. LIVESEY: I thought we had all thanked Mr. Archer when we discussed his paper, but if not we can readily rectify that omission.

Mr. ROBERTS: Certainly, with your permission, Mr. President, I will propose that we accord Mr. Archer a very hearty vote of thanks for his excellent paper. Mr. Smith seconded this, and the proposition having been carried, the proceedings terminated.

J. ALEX. TODD, *Hon. Sec.*

VETERINARY MEDICAL ASSOCIATION OF IRELAND.

A general meeting was held at the Gresham Hotel, on Friday, May 26th. The President (Prof. A. E. Mettam) occupied the chair, and there were also present Messrs. J. A. Jordan, W. Chambers, Prof. J. F. Craig (Hon. Treasurer), P. J. Howard, L. M. Magee, Lieut.-Col. Charles Steel, James McKenny, W. H. Wilkinson, J. Doyle, Prof. J. O'Connor, and A. Watson (Hon. Sec.).

The minutes of the last meeting as printed and circulated were adopted, on the motion of Mr. W. Chambers, seconded by Lieut.-Col. Steel.

Apologies for inability to attend were received from Messrs. J. J. Vahey, J. A. Thompson, Finlay Kerr, A. C. Duncan, P. D. Reavy, J. E. Johnston, A. F. Walshe, F. A. Heney, and M. Hedley.

REPORT OF COUNCIL.

A meeting of the Council was held on April 3rd. The President occupied the chair, and there were also present Messrs. James McKenny, J. B. Dunlop, W. H. Wilkinson, Prof. Craig, Prof. O'Connor, and A. Watson.

The meeting ordered that a letter of condolence with the family of the late Mr. T. D. Lambert be sent to Mrs. Lambert in the name of the Association.

The Secretary mentioned that Mr. Cargill Patrick had met with an accident in the hunting field, and was directed to write a letter of sympathy and hope for his speedy recovery.

A letter was read from Mr. Cargill Patrick choosing to act as Vice-President of the Association, he having been elected also a member of the Council, and Mr. Heney was unanimously co-opted to the position on the Council rendered vacant by Mr. Patrick's selection.

A letter was read from Mr. John Holland acknowledging a vote of thanks passed at last general meeting for the manner in which he had acted as President of the Association.

A letter was read from Mr. Hannan in reply to a request to reconsider his resignation, in which there was no affirmative answer.

A discussion took place on letters from Prof. Gofton and Mr. Jordan, Belfast, relative to the proposed amalgamation of veterinary societies. It was suggested that an extraordinary meeting of the three Irish Societies be held on April 19, 1911, at 4 o'clock at the Royal Veterinary College of Ireland, and that Dr. Bradley be invited to address the meeting.

The question of the Congress of the Royal Institute of Public Health to be held in Dublin in August was before the meeting, and after full consideration it was resolved to refer the matter to the extraordinary meeting, some names being suggested to act on a Committee of Management, and as Vice-Presidents.

Mr. Emery, of Belfast, wrote regretting his inability to act as representative of the Association at the Sanitary Congress to be held in Belfast in July. The Secretary was instructed to ask Mr. Thompson, of Lurgan, to attend the Congress as representing the Association.

A letter was read from the Royal College of Veterinary Surgeons thanking the Association for sending a copy of counsel's opinion *re* Petrol Tax, etc.

The Secretary brought before the Council a public report of a case in which the Donegal Board of Guardians and District Council appointed a layman as Inspector under the Dairies, Cowsheds, and Milkshops (Ireland) Order. The Council took no action in the matter, as it was not a veterinary appointment.

A letter was read from the North of Ireland Veterinary Medical Association, relative to the desirability of a uniform system of meat inspection in Ireland. The Council appreciated the spirit of the letter, regarding the

subject as a suitable one for discussion at the coming Congresses in Belfast and Dublin, and the Secretary of the North of Ireland Veterinary Medical Association was suggested as a possible contributor of a paper on the subject.

The Secretary was requested to call on Messrs. Duncan and Carlisle with reference to the Trusteeship of the Association, and have a deed drawn up in legal form.

The matter of the Insurance of the Sire "Lad O' Wax," was before the Council and postponed to the next meeting.

Meeting of Council held on May 10th. The President occupied the chair, and there were also present: Prof. O'Connor, Prof. Craig, Messrs. Chambers, James McKenny, Lieut.-Col. Steel, W. H. Wilkinson, W. Cargill Patrick, R. H. Lambert, and A. Watson.

A letter was read from Capt. W. A. Pallin informing the Council that as he was under orders to sail for South Africa he was resigning his position on the Council. The resignation was regretfully accepted, and it was ordered that Capt. Pallin be placed on the list of corresponding members.

A letter was read from Mr. F. A. Heney thanking the Council for co-opting him on the Council, and accepting the position.

A letter was read from Mr. W. H. Lambert thanking the Association for the vote of confidence with the relatives of the late Mr. T. D. Lambert.

Mr. Cargill Patrick wrote thanking the Council for their resolution of sympathy with him in his accident.

A letter was read from Mr. Walshe, M.R.C.V.S., Carlow, requesting a copy of counsel's opinion *re* Finance Act, 1910, as a prosecution was pending.

Mr. P. J. Byrne, solicitor, Carlow, wrote stating he was acting for Mr. Walshe, and made a similar request, and also asked if the Council could see its way to defend the case. After careful consideration the Council regretfully decided that the state of their funds would not allow them to fight this case. Mr. McKenny dissenting.

A letter was read from Mr. J. A. Thompson, F.R.C.V.S., Lurgan, acceding to the request of the Council to attend the Sanitary Congress at Belfast in July as delegate from the Association.

Mr. J. A. Jordan, Belfast, wrote expressing his regret that he was unable to adopt the suggestion of the Council that he would provide a paper on "The System of Meat Inspection in Ireland."

The Royal College of Veterinary Surgeons wrote informing the Council that the copy of Counsel's opinion *re* Finance Act, 1910, had been placed before the Parliamentary Committee, and that the Chancellor of the Exchequer had intimated that he could not receive any deputation about the matter.

The Council ordered that a resolution standing in the names of Messrs. Watson and Wilkinson, having reference to the proposed amalgamation of veterinary societies, should be considered at the general meeting.

It was decided that the next general meeting of the Association be held on 26th May at the Gresham Hotel, and papers were arranged therefore.

The matter of the insurance of the sire "Lad O' Wax" was brought before the Council, and they decided that the matter was outside their jurisdiction.

Mr. P. SMALL, M.R.C.V.S., Clones, was nominated for membership of the Association.

A conjoint meeting of the members of the Central Veterinary Medical Association, the North of Ireland Veterinary Medical Association, and the Veterinary Medical Association was held at the Royal Veterinary College, Dublin, Principal Mettam occupied the chair.

The meeting was held to consider, amongst other

matters, the proposed Amalgamation of Veterinary Societies.

The CHAIRMAN explained the objects of the meeting and introduced Dr. O. Charnock Bradley, of Edinburgh.

Dr. BRADLEY gave the meeting an eloquent and lucid explanation of the details of the scheme, and was heartily applauded.

The meeting was also addressed by Messrs. James McKenny, E. C. Winter, Prof. Duncan, J. A. Thompson, J. Holland and M. Hedley.

The CHAIRMAN brought the proceedings to a conclusion by remarking that it would be as well to let the subject stand till such time as matters could be brought to an amicable and satisfactory conclusion.

Mr. McKENNY drew attention to a portion of the report in which dissent he had taken to one matter was recorded, viz., they had gone to the expense of submitting a subject to the Solicitor, and took counsel's opinion upon it, and then they afterwards said that for want of funds they could not take action. That seemed to him as though they were stultifying themselves.

The HON. SEC.: You don't question that the minutes are correct?

Mr. McKENNY: No, and I may say this, it is very difficult to make a report of Council, but I think that it is a magnificent one. However, that entry about the funds ought to be deleted.

The PRESIDENT: What is the objection to publishing the fact that we haven't any available funds. It is no disgrace, poverty.

Mr. McKENNY: But it isn't true.

The SECRETARY pointed out that Mr. McKenny would have an opportunity of discussing the subject later on, as there was another letter from Mr. Walshe asking them to go on with the case.

Mr. WILKINSON proposed that the reports be adopted.

Mr. HOWARD seconded, and the motion was carried.

PROFESSIONAL ETIQUETTE.

The meeting discussed a case of alleged breach of professional etiquette. It was stated the gentlemen in question had explained that he had acted without thought, and would take steps to withdraw the matter complained of. The Secretary was instructed to furnish the details to the Registration Committee.

PETROL TAX.

The PRESIDENT briefly explained that a letter had been received by the R.C.V.S. from Mr. Lloyd George, and the tone and the substance of the letter conveyed that he was not going to have any more bother with the veterinary profession. The Council of the Royal College were for taking it literally and accepting this letter as the final word, but on the proposition of someone it was left open, and so they were going to again approach Mr. Lloyd George. A Labour Member of Parliament was interesting himself in the matter. That was the position now.

The SECRETARY: Mr. Howard, who is a personal friend of some of the Irish members, might do something.

The PRESIDENT added that the letter was very strong and pure "Georgese." He (the Chancellor) was going to have nothing more to do with them; they were too puny a people to influence any votes, and that was the interest Mr. Lloyd George had.

MOTOR CAR PROSECUTION.

Mr. A. WALSH, Carlow, wrote as follows:—

"Dear Mr. Watson,—My case *re* motor car dwindled down to 'neglect to make a declaration.' I understand the medical rebate will come on later. I will not be able to attend meeting to-morrow night, and will ask you to ascertain the views of the Association on the

matter. It is a matter of principle, and one the Association should defend to uphold the dignity of the profession. If a secretary of a County Council can put us down as not being medical practitioners then we deserve what we get. I shall be glad to hear from you and to know the views of the Association on the matter at your earliest convenience."

The SECRETARY stated Mr. Walshe was fined £20 for neglect to make a declaration.

Mr. HOWARD said surely the fact of his being a veterinary surgeon did not excuse him from obeying the law of the land. Mr. Walshe brought himself within the law by not registering the car, and he had to toe the line.

The SECRETARY: That part of it is finished with, but he says the question of being a medical man will come on for adjudication later on. We have the fact that Mr. Freeman, of Dublin, Mr. Moffett, of Galway, and Mr. Donnelly, of Drogheda, have been accepted as medical practitioners in their separate counties. Mr. Walshe's case is on the same lines as theirs. I have informed him of that.

The PRESIDENT said it was more likely to be settled by an amicable talk between Mr. Walshe and the Secretary of the County Council than by their taking it up. It was hardly likely this secretary would take up an attitude different from other officials, as it would only be making trouble for himself. (Hear, hear.)

The SECRETARY was instructed to draw Mr. Walshe's attention to the decision in Mr. Allen's case *re* juries, and to the fact that Messrs. Freeman, Moffett, and Donnelly had been recognised as medical practitioners by the respective Councils.

AFFILIATION SCHEME.

Mr. A. WATSON rose to propose the following resolution:—

"That having heard Dr. Bradley *re* Affiliation of the Veterinary Associations of Great Britain and Ireland with the National Veterinary Association, the Veterinary Medical Association of Ireland take the necessary steps to affiliate, as we believe it is in the best interests of the profession and of all the Members of our Association."

Mr. WATSON said it was not his intention to labour the subject, as all present heard Dr. Bradley in a most eloquent fashion prove the many good things that would accrue from affiliation. In a word, the idea of this scheme was to create a body on similar lines to the British Medical Association. It undoubtedly was most desirable that some such body should exist in the veterinary profession to guide them and to protect their interests. This should especially be the case, inasmuch as affiliation did not represent a very large sum. If it meant the wealth of the nation as represented by the veterinary profession in Ireland he would agree they ought to pause, but inasmuch as under the rules which were proposed it only meant 1/- per head it was worth the experiment. They had nominally on their books a membership of something like 150, but he would ask the members to remember it was not meant they had to pay a fee of 1/- on the 150, for they must remember that under Clause 9 of their rules it said "each member shall pay in advance an annual subscription of 10/6, which shall fall due on the 1st January in each year; no member shall be entitled to exercise any of the privileges of the Association who shall be in arrear with such subscription." Accordingly it meant a fee of 1/- only for such number as had paid their 10/6 in advance. He had obtained from the Treasurer a report of the number who had paid their dues up to date, and consequently were "in benefit." For the year 1911 there were only 36 members at the time the Treasurer made up the list; there were some few added since.

In 1910 there were 79, and in 1909 there were 70. His virile antagonist—(laughter)—on this subject would hardly say that such an Association as theirs could hesitate to give 36/- a year to carry on the experiment. If they affiliated it did not necessarily mean that they must affiliate for all time. They could at the end of any year send in their resignation and their affiliation would cease. He would appeal very specially to Mr. McKenny not to be too hostile because his own pet theories and his own pet rules were not accepted by the Committee in charge of this scheme; not to be too antagonistic, but to remember that as an experiment at the cost of 36/- or £2 it was well worth trying. If at the end of one, two, or three years they came to the conclusion, as Mr. McKenny put it, that "it was all a fraud, that it was only a recruiting ground for pulling members into the National," they could send in their resignation and their liability ceased. He had pleasure in proposing the resolution. (Hear, hear.)

Mr. W. H. WILKINSON said he had pleasure in seconding. They had admitted they thought there was a necessity for some such action by submitting an alternative scheme, and he thought Dr. Bradley made a very honest attempt to meet their wishes. He had read the proposals through very carefully, and really did not find any material differences between them. He hoped this amalgamation would be brought about.

Mr. McKENNY observed that Mr. Watson had alluded to him, and he hoped in such a very important matter as that, neither Mr. Watson nor he, to please themselves, would do an injury to the profession. Dr. Bradley set forth some very magnificent benefits to be derived, but unfortunately those benefits when they came to test them, were admittedly only imaginary. They were things to be hoped for, but the reality was not there. The only benefit they had to deal with was simply that of becoming affiliated to the National, so that the National might obtain so much money, and, as he told Dr. Bradley, make the Association, recruiting grounds for the National. This Association would receive no benefit from the proposed rules. The only possible thing that Dr. Bradley held out to them was that, instead of the members having to pay 10/6 to the National, 7/6 would be the fee. They had a joint conference of the Irish Associations to hear Dr. Bradley, and after hearing him they said not one word in his favour, simply because the scheme had no benefits to offer them, and they were not going to stultify themselves for an imaginary prospect; they were not going to grasp at the shadow and let the reality go. The reality was the amalgamation of the Associations. It was not affiliation with the National, but the amalgamation that gave the union and strength to the whole profession that they were really desirous of seeing accomplished. He truly believed that amalgamation was a magnificent thing; it would realise all the benefits that Dr. Bradley set forth to them, but if they affiliated it would crush for some years that which they really wanted—amalgamation—and therefore it would be a most injurious and injudicious thing to pass that resolution.

Mr. HOWARD was sorry he had not had the pleasure of listening to the exposition of the rules and regulations by Dr. Bradley, but he remembered that he (Mr. Howard) was one of the first to suggest the idea of affiliation when the amalgamation scheme was originally launched. He suggested that the only way to work it was by a scheme of affiliation. He thought there was some mistake in the opinion given them by Mr. Watson as to what the affiliation fees would be. He thought the fees would be the fees of whatever member of their Association desired to join the National. It was not necessary that they should pay for 36 or 46 or 100 members if they were not going to become members. That was the trouble preventing an amicable solution

—the fact that they had a great many members who did not care a straw whether there was a National or not, and did not want to become members of it. He would be perfectly satisfied as a member of that Association if it was used as a recruiting ground for the National. It would do a tremendous good if every veterinary surgeon in the country would become a member. The scheme submitted up to the present, however, would not help to encourage their members to become members of the National.

Mr. WATSON disagreed with Mr. Howard as to the affiliation fee.

Mr. HOWARD declared the affiliation fee of 1/- for every subscribing member from the division meant subscribing member of the National. But they were not going to pay an affiliation fee in respect of members who did not want to join the National. Mr. McKenny and others objected to this Association being utilised as a recruiting ground. They would at least get the benefit of being able to get into the National at 7/6 instead of 10/-.

Mr. McKENNY: I do not object. I say that the whole effect of the scheme is to make us recruiting grounds, and that that is all it does.

Mr. HOWARD, continuing, said he did not think the suggested rules would meet the object desired, and he thought they might take their time in Ireland. It was of more importance to the other side of the Channel, and they had not yet found a happy solution.

The PRESIDENT: Will you propose as an amendment that the matter be deferred until we have the report of the next National meeting at Carnarvon? Then you will see what they are going to propose.

Mr. HOWARD: I was simply endeavouring to give an explanation of why I would propose that policy. I wish to formally propose that any action be deferred until we see the report of the Joint Committee to the next meeting of the National Association.

Mr. McKENNY seconded. There voted for the amendment, 8; and against, 2; and the amendment was then put as the substantive motion and carried.

The PRESIDENT: I think that is just the Premier's attitude of "wait and see."

NEW MEMBERS.

The following gentlemen were elected members of the Association:—

Lieut.-Col. J. MOORE, F.V.O., Irish Command, Island Bridge Barracks, Dublin, proposed by Prof. Mettam, seconded by Mr. James McKenny.

Mr. J. DODD, M.R.C.V.S., Swinford, Co. Mayo, by Mr. James McKenny, seconded by Prof. Craig.

Mr. F. B. HAYES, M.R.C.V.S., Royal Veterinary College, Ballsbridge, Dublin, by Mr. James McKenny, seconded by Prof. Craig.

Mr. J. J. O'BRIEN, Belmullet, by Prof. O'Connor, seconded by Prof. Craig.

Mr. P. SMALL, M.R.C.V.S., Clones, by Prof. Craig, seconded by Prof. O'Connor.

Mr. GEO. W. TYSON, D.A.T.I., by Mr. McKenny, seconded by Prof. Craig.

Mr. J. B. HARE, Navan, was nominated by Mr. L. M. Magee, seconded by Mr. J. McKenny, the ballot to take place at next meeting.

(To be continued).

At a meeting of the Tuberculosis (Animals) Committee, it was unanimously resolved "That this Committee, having considered the final report of the Royal Commission on Tuberculosis, respectfully press the Board of Agriculture to bring into operation the Tuberculosis Order of May 27th, 1910; but the compensation to be provided either out of the Development Fund or from other Imperial sources, and not from the local rates."

ROYAL COUNTIES VETERINARY MEDICAL ASSOCIATION.

It being Coronation year, the Association had decided that their summer meeting, on Thursday, July 20, should take the form of a river trip; and the arrangements were carried out with the most perfect success, the management being entrusted to a sub-committee consisting of Messrs. E. J. Mellett, President for the year, Henley; Percy J. Simpson, Maidenhead; and Geo. P. Male, Hon. Sec. and Treas., Reading. The party assembled at Maidenhead Station shortly after 1 o'clock and were driven to Boulter's Lock, where they boarded Bond's fine launch, "Empress of India," and went up the river to Henley, which was reached in time to allow of a run up the backwater in front of Park Place, where many house boats were moored on either side. The exquisite scenery (which was new to a few of the party) was seen at its best on a perfect July day, the heat of which was tempered by the fleecy clouds and a pleasant breeze. Luncheon and tea were served on board: at the close of the former the President submitted the toast of His Majesty the King.

The business of the meeting was conducted on deck, President in the chair.

The Hon. Sec. read apologies from the following members and friends who were unable to attend: Profs. McCall and Macqueen; Messrs. Anderson, W. Wilson, Hanks, Hurndall, Owen, East, Tennant, Jagger, Todd, Hughes, Verney, Standley, Pauer, Page Bull, Shipley, King, Butters, and Major Harris.

The following gentlemen were nominated for membership:—

Mr. J. H. PARKER, M.R.C.V.S., Faringdon, proposed by Mr. P. J. Simpson, seconded by the President.

Mr. T. SEALEY GREEN, M.R.C.V.S., Tring, by Mr. T. W. Lepper, seconded by Mr. D. Wyllie.

It was agreed that the next place of meeting should be Red Lion Square.

A vote of thanks to the President for presiding concluded this part of the meeting.

The party was, for many causes, smaller than had been expected. Those present included: Members—Messrs. E. J. Mellett (president), Sidney Villar, G. P. Male (hon. secretary and treasurer), T. W. Lepper, P. J. Simpson, S. H. Slocock, J. Willett, J. Hatch, and D. Wyllie; and visitors—Mrs. Mellett, Mrs. Male, Prof. and Mrs. Wooldridge, Mrs. Villar, Mrs. T. W. Lepper, Mrs. P. J. Simpson, Mrs. Slocock, Mrs. Willett, Mrs. Wyllie, Mr. and Mrs. J. H. Parker, Miss Habgood, Mr. J. Budgen, Mr. Cobb, and Miss Fitzjohn.

G. P. MALE, Hon. Sec.

NATIONAL VETERINARY ASSOCIATION.

ANNUAL BANQUET.

The annual banquet was held at the Sportsman Hotel, Carnarvon, on Wednesday evening, July 27, under the Chairmanship of the President, Mr. Salusbury Price.

Following the usual loyal toasts, Mr. J. T. SHARE-JONES proposed "The Mayor and Corporation of Carnarvon." In doing so he said there was no question but that antiquity was a thing which appealed to every man and woman with a spark of human nature in them in a manner which could not be expressed in words. That being so he felt sure it had been a source of great delight to each and every member of the National Veterinary Association to have been privileged to hold their meeting in Carnarvon. In his opinion there was no town which possessed the glorious traditions associated with Carnarvon. The Association was extremely grate-

ful to the Mayor, and congratulated him and his lady upon the signal honour which had been conferred upon them by His Majesty the King.

The DEPUTY MAYOR (Mr. Nath Roberts) having responded, the toast of "The Army, Navy, and Allied Forces" was proposed by Mr. W. Woods.

Capt. PALLIN, in reply, assured the members that those who were in the Army Veterinary Corps did not forget that the improved conditions under which they now served were due to a great extent to the work done by the National Veterinary Association and others in the cause. For the past two years he had been stationed at Woolwich where he saw more of the men (subordinates) coming into the Corps than of the officers, as the men were trained at the depot there. He could only say that the Corps was popular and was attracting a very good class of man. It was a great improvement on former times for officers to have their own men to nurse and look after their cases, and he had no doubt that the benefit of the men's services would be even more evident on service than in times of peace.

Dr. PARRY, J.P., then proposed the toast of the evening—"The National Veterinary Association." In doing so he said he did not know why he should have been asked to propose the toast unless it was that he was the only medical man in the town who owned a horse! (Cheers). The importance of an Association like the National Veterinary grew year by year, and he strongly urged all veterinary surgeons to support it in order to see they obtained justice from the community. The community in the future was going to ask more of the medical and veterinary professions than it had ever done in the past, and it was of the utmost importance that the members of those professions should weld themselves together and have a clear idea as to what their rights and responsibilities to the public were. (Hear, hear.) Medical science in the past had directed itself to the treatment of disease, but latterly medical men had been patriotic enough to expect their reward in another world, and were now making efforts to prevent disease. That would be to a great extent the science of the future, not only in the medical but in the veterinary profession.

The PRESIDENT, in responding to the toast, referred to the recent report of the Royal Commission on Tuberculosis, and said that if the public would only support and use the veterinary profession, veterinary surgeons would guarantee to rid the country of tuberculous diseases amongst animals.

Dr. PARRY EDWARDS, in replying to the toast of "The Guests," proposed by Mr. Henry Taylor, said he felt convinced that unless the Medical Officers of Health and veterinary surgeons were joined hand in hand there was no possibility of ridding this country of that foul disease, tuberculosis. With regard to meat inspection, from his experience of travelling about certain parts of the country, he could say that meat inspection was, to use a mild term, an absolute farce; and until veterinary surgeons were put in their proper position with regard to the matter he did not see any chance of improvement. (Hear, hear.)

The toast of "The Ladies" having been proposed by Dr. Charnock Bradley, was eloquently replied to by the Lady Mayoress.

THE NORTH WALES SOCIETY'S EXCURSION.

On Friday, 28th, members of N.V.A. and their friends were invited by the North Wales Veterinary Society to a coaching excursion amongst the mountain passes. The previous day had been wet, and the mountains shrouded in clouds, and the morning of Friday was not bright, but half-an-hour after leaving Carnarvon we were in sunshine, and with beautifully clear air and light breeze the day could not have been finer. The road chosen was to

the S.E. from Carnarvon, past the old parish church at Llanbeblig, rising steadily till shortly before the mountains shut in on the road there was a magnificent prospect of the Isle of Anglesey, Carnarvon Bay, and on the far horizon the shores of Ireland. Then for miles through constantly varying mountain scenery till a short halt at a hostelry overlooking Llyn Quellyn, where some of us recognised the legend "Ind, Coope"—and deliciously cool the nectar was. The next halt was at Beddegeleert, where Luncheon was served at the Saracen's Head Hotel, and the health of Mr. R. S. Rowlands (President), and Mr. L. W. Wynn Lloyd (Secretary) was given with musical honours.

From Beddegeleert the road runs N.E. through the picturesque Vale of Gwynant, past Llyn-y-ddinas and Llyn Gwynant. At Pen-y-gwryd there is another cool cellar. Here a road goes eastward to Capel Curig and Bettws-y-coed. Our road was westward, up to Pan-y-pass (Gorphwysfa), and thence down the narrow and rugged pass of Llanberis, with its sides towering up nearly 3000ft., the crest of Snowdon close above us on the left but not visible. Half-a-dozen miles brought us to the Hotel where tea was served, and another hour brought us to Carnarvon and the close of a delightful excursion through scenery probably unequalled in the British Isles.

There was the usual display of Instruments, etc., in the Guildhall, on Wednesday and Thursday: Messrs. Arnold and Sons, Willows, Francis, and Co., Hewlett and Son, Huish and Co., and Messrs. Favre, with Hauptner's instruments and appliances, were represented.

Royal Sanitary Institute Congress.

MEAT INSPECTION.

At the concluding session of the Royal Sanitary Institute Congress at Belfast on Friday, 28th ult.,

Mr. W. G. Barnes, chief veterinary inspector, Metropolitan Cattle Market, Islington, contended that in many rural districts meat inspection was theory instead of practice. The system in this country was most unsatisfactory, and must continue so until those authorities responsible for public health ignored trade objections and vested interests, and made legislation under which the standard of inspection must be uniform throughout the whole country. They must also see that the existing regulations with regard to imported meat were uniformly carried out. Hence the necessity for an international conference for the formation of such regulations as should be binding on all the Governments concerned.

Dr. W. Hanna, assistant medical officer of health for Liverpool, said that the bulk of the foreign meat reaching this country was free from disease. Searching examination made by the Liverpool sanitary authorities of Chinese pork satisfied them that it was fully as sound as any bred in this country. A considerable improvement in those imported pigs as regards disease was already manifesting itself as the result of stricter and more systematic examination carried out in China. He would like to see some uniformity with regard to meat inspection generally, with proper stamping of meat as regards its condition on slaughter.

Mr. James Jordan, Belfast, contended that the marking of meat was the only practicable method of ensuring the efficient inspection of meat shops.

Dr. Collingridge, London, said it would be far better if they did not bother with the marking of foreign meat. Let them confine marking to sound healthy meat production at home.—*The Times*.

PARLIAMENTARY.

In the House of Commons, on Wednesday, July 26.

MILK AND TUBERCULOSIS.

Mr. C. BATHURST (Wilts, Wilton, Opp.) asked the President of the Local Government Board if he would say upon what day he proposed to introduce the Milk and Dairies Bill; and whether any of the provisions of such Bill had been modified in consequence of the recently issued Final Report of the Royal Commission on Human and Animal Tuberculosis.

Mr. BURNS (Battersea).—Due notice will be given of the introduction of the Bill. I am considering what modifications in the Bill may be necessary by reason of the Report of the Royal Commission.

Mr. C. BATHURST asked the President of the Local Government Board whether he was conversant with the experiments which had been recently conducted on human beings in Germany in order to test the extent of the risk resulting from the human consumption of milk obtained from cows infected with tuberculosis of the udder, and with the report published last year by the Imperial Health Office of Germany based upon such experiments; whether, in the light of that Report, he was advised by the medical experts of his Department that the drinking of, as distinct from the inoculation with, cows' milk containing tubercule bacilli was calculated seriously to endanger human health even in the case of children; and whether, in view of the absence of deleterious effects resulting from most of the feeding experiments conducted by the Royal Commission on Human and Animal Tuberculosis, he would, in order to allay undue alarm upon this subject, cause further scien-

tific investigations to be made before taking drastic measures in respect of the national milk supply on a possibly false hypothesis.

Mr. BURNS.—The experiments referred to were merely observations on the medical history of 360 persons (151 children) who were stated to have consumed tuberculous milk. My advisers agree with the finding of the Royal Commission on Tuberculosis to the effect that "measures for securing the prevention of ingestion of living bovine tubercle bacilli with milk would greatly reduce the number of cases of abdominal and cervical gland tuberculosis in children," and there is nothing in the facts contained in the German report referred to in the question which is incompatible with this conclusion. It would be superfluous, in view of the many years' work of the Royal Commission, to cause further scientific investigation to be made on the points which they have definitely settled.

Mr. C. BATHURST asked whether among the medical profession it was not universally admitted that the disease was due more to predisposition caused by insufficiency of milk than to the presence of bovine germs in the milk itself.

Mr. BURNS said that view was held by some members of the profession entitled to respect, but others equally entitled to respect held a very opposite view.

PROTECTION OF ANIMALS BILL.

In the House of Lords on Thursday, July 27.

On the motion of Lord Saye and Sele the House went into Committee on the Protection of Animals Bill, the Earl of Donoughmore in the Chair.

On Clause 1 (Offences of Cruelty),

The EARL OF CROMER said that, as it appeared that vivisectionists were not to be liable to prosecution under the bill to any greater extent than the present law permitted, he would like to say, as President of the Research Defence Society, that the members of that Society not only did not oppose the Bill, but that they were in accord with the general object which it sought to attain. They welcomed any reasonable attempt to stop wanton cruelty. He thought the noble lord who was promoting the Bill had exercised a wise discretion in leaving the vivisection question alone. It would manifestly be very undesirable to attempt to deal with a controversial matter of that sort until the Royal Commission had issued its report, which, he earnestly hoped, would not be very much longer delayed.

The Clause was ordered to stand part of the Bill.

On Clause 6 (Poisoned grain and flesh, etc.),

Lord SAYE and SELE moved to omit certain words in Sub-section (b) and to insert the following proviso:—"Provided that in any proceedings under paragraph (b) of this section it shall be a defence that the poison was placed by the accused for the purpose of destroying rats, mice, or other small vermin, and that he took all reasonable precautions to prevent access thereto of dogs, cats, fowls, or other domestic animals."

The amendment was agreed to.

Earl CARRINGTON moved the omission of Clause 8 (Extension of powers of Board of Agriculture and Fisheries with respect to the making of Orders), on the ground that the purpose in view was covered by a Bill which had passed both Houses and was now awaiting the Royal Assent.

The amendment was agreed to.

On Clause 9 (Inspection of traps),

The EARL of DERBY expressed the opinion that the phrase "spring trap" required stricter definition. Both mouse-traps and mole-traps were spring traps, but it was surely not intended that they should be covered by the clause?

The MARQUESS of LANSDOWNE failed to see how it would be possible to enforce the provision that some competent person should inspect the trap "at least once in every 12 hours."

The EARL of DERBY moved the omission of the Clause.

The motion was agreed to.

Lord CLONBROCK moved an amendment setting forth that nothing in this Act should prevent owners or occupiers of land in Ireland from laying down poisonous matter after proper public notice. This was for the protection of farmers against loss from wandering dogs.

Lord HERSHELL said the amendment was in accordance with the views of the Irish Board of Agriculture.

The amendment with verbal alterations was agreed to, and the Bill as amended was reported to the House.

The Crochmore Donkey Case: Slander Action Settled.

In the First Division of the Court of Session on Friday, 21st ult., before the Lord President and Lords Kinnear, Johnston, and Mackenzie, intimation was made that a settlement had been effected in the action by James Lindsay, M.R.C.V.S., 35 Whitesands, Dumfries, against John Henry Ferguson of Crochmore, Irongray, which was set down for trial by a jury on Tuesday last. The pursuer concluded for the payment of £500 damages in respect of slander uttered by the defender in connection with a donkey at Crochmore, which the pursuer examined. The slander arose in a small debt action for damages for alleged slander which the defender raised against the pursuer in which the statements complained

of were made. Further, the pursuer complained that the action was dropped, and he was thereby deprived of an opportunity of answering the statements. The defender denied the slander and pleaded privilege.

In terms of the joint minute by which the action has been taken out of Court, the defender agrees to pay the pursuer £50 of damages and expenses, judicial and extrajudicial. He further sent the following letter to the pursuer:

To Mr. James Lindsay, M.R.C.V.S., Dumfries.

Sir,—With reference to the action you have raised against me in the Court of Session for damages for slander in respect that I accused you of having falsely, and well knowing the same to be false, granted the following certificate: "I hereby certify that I have this day at the instance of J. H. Ferguson, Esq., of Crochmore, Irongray, Dumfries, examined a donkey, seven years old, and find the said animal going sound, but in poor condition, suffering from sores on its back, and totally unfit for work at present." I hereby unreservedly withdraw said accusation, express my regret, and apologise therefor.—Your obedient servant,

(Signed) J. HY. FERGUSON.

I adopt the above as holograph.

(Signed) J. H. FERGUSON.

Dumfries, 17th July, 1911.

Agents for the pursuer—Messrs. Adamson and Blacklock, Dumfries; for defender—Mr. W. Nicholson, jun., Kirkcudbright.—*Dumfries and Galloway Standard and Advertiser.*

The Royal Veterinary College.

At the annual meeting of the Royal Veterinary College, Mr. Albert Brassey presiding, said there had been a considerable falling off in the number of students—namely, 35, compared with 41 last year. Whether that decrease was due to the increased use of motor traction and the restricted demand for horses he was not prepared to say, but the result certainly pointed in that direction. Financially they were all right, the income exceeding the expenditure by £25. The Government grant had been increased from £800 last year to £1,300 this year, and the Royal Agricultural Society had supplemented this by an additional grant of £200 for three years to defray the cost of research regarding animal disease. The Duke of Bedford and Lord Crewe were elected vice-presidents, and Major-General Pringle, Colonel Vaughan Lee, Lord Harlech, Mr. Stewart Stockman, Chief Veterinary Officer to the Board of Agriculture and Fisheries, and Mr. F. Reynard were appointed governors.

Personal.

DR. J. G. RUTHERFORD.

Federal agriculture at Ottawa loses an invaluable servant through the resignation of Dr. J. G. Rutherford, Dominion Veterinary Director-General and Live-stock Commissioner. John Gunion Rutherford first saw the light of day in Peeblesshire, Scotland, having had the fortune to be born a minister's son. He was educated in Glasgow, and arrived in Canada, September, 1875. Like so many of his countrymen, he found in the Dominion a field to develop his native calibre, and his career has been marked by a brilliant course of professional and administrative success. From 1889 to 1901 he practised veterinary medicine, was elected to the Manitoba Legislature in 1892, serving till 1896. In 1897 he was elected to the Dominion House of Commons. Subsequently entering the Department of Agriculture, he was in 1904 made Veterinary Director-General, and in 1906 was called to fill a dual capacity, acting as Veteri-

nary Director-General and Livestock Commissioner. In both spheres he has achieved conspicuous success. His work in suppressing contagious diseases of animals in the West and elsewhere has been thoroughgoing and proportionately successful. As Live-stock Commissioner, he has succeeded in retaining the goodwill and respect of stockmen the country over, while serving their interests judiciously at every turn. At conventions his advice has always been sought, and almost invariably followed. As a veterinarian, he ranks among the most eminent in America. He was last year president of the American Veterinary Medical Association, and was, if we mistake not, the prime mover in securing the appointment of the International Commission on Tuberculosis, on which he served most effectively. The strain of work has told, however, upon his health, which has not been the best the last few years, though we are definitely advised that this is not the cause of his resignation, which he was asked, but declined to reconsider.

HOWARD—MACKERCHAR.—At Wellington, N.Z., on Saturday, June 17, Edmund Carlisle, M.R.C.V.S. (Government Veterinarian), eldest son of the late Edmund George Howard, F.R.C.S., F.R.S.E., Clitheroe, Lancashire, England, to Margaret, eldest daughter of Donald MacKerchar, Stirling, Scotland.

PAGE—BLAKEWAY.—On the 1st inst., at the Parish Church, Chaddesley Corbett, by the Rev. G. Griffith Williams, vicar, Robert Page, second son of John Page, Esq., of Hill Pool, Chaddesley Corbett, to Hilda, only daughter of John Blakeway, F.R.C.V.S., late of Birmingham.

OBITUARY.

Mr. William Carless, M.R.C.V.S.

By the death of Mr. Carless, of Stafford, which occurred on Thursday, 13th July, the profession lost one of its oldest and best practitioners. His great experience and sound judgment gained for him a very extensive practice and a high reputation in the Midlands, where the Carless family has been engaged in veterinary work for a century and a half.

Mr. Carless frequently acted as Veterinary Surgeon at Agricultural Shows, he was veterinary adviser to the Staffordshire County Council, a local inspector to the Board of Agriculture and to the Stafford Town Council. He was, until quite recently, when his health failed, a regular attendant at the Midland V.M.S., and when he spoke it was always to add some reliable facts or shrewd criticism to the debates.

Those who knew him outside of his profession entertained the highest respect for the deceased gentleman who under a reserved manner hid a warm heart. He took little or no part in public life, which perhaps was a loss, as his commonsense and absolute integrity would have given him a weighty influence on any authority.

Mr. Carless' death was not unexpected, and followed a long and painful illness. He leaves three daughters and a son. His age was 71. The practice will be continued by his partner, Mr. H. Thackeray.

From *The Staffordshire Mercury* we quote a notice of the funeral which further marks the respect felt by everyone:—

The funeral of Mr. William Carless, M.R.C.V.S., of Eastgate, Stafford, took place on Saturday, July 15th. Prior to the interment a service was held at St. Austin's Church, where a Solemn Requiem was sung, unaccompanied, to the Mechlin chant, by the Rev. Canon Keating. The Rev. J. M. Lillis acted as Master of the Ceremonies. After the Mass, Canon Keating delivered a short address, eulogizing the character of the deceased

and his many good qualities. Subsequently the interment took place at the Cemetery, the coffin being placed in the family vault. The last rites were performed by the Rev. Canon Keating and the Rev. J. M. Lillis. The mourners were Miss Clare Carless (daughter), Mr. and Mrs. Rupert Evans, Mr. and Mrs. Thackeray, Mr. Reginald Carless (Stafford), and Mr. W. S. Carless (Worcester), nephews; and Miss Madge Carless (niece). Among those who attended the service at church or were present at the graveside were Dr. C. Reid, Mr. J. E. Evans, the Mayor of Stafford (Ald. T. Westhead), Ald. E. W. Taylor, the Mayor of Newcastle (Mr. R. C. Trigger, F.R.C.V.S.), Mr. W. Coe, M.R.C.V.S., (Stoke-on-Trent), Mr. W. Towers Mynors (representing the Earl of Shrewsbury and Talbot), Mr. G. E. Nuttall, Mr. G. S. Parker, Mr. T. Coulthwaite (Hednesford), Mr. W. Sampson (Stowe), and Mr. Louis Sandy. Many floral tributes were sent. As a mark of respect to the memory of the deceased, who held an official appointment under the Corporation, the Union Jack was placed at half-mast at the Guildhall.

PROFESSIONAL FEES.

Sir,

I, like Mr. Henry J. Pope, of Kensington, was very much interested in the report of the South Durham and North Yorkshire V.M.A. and am glad that Society has had the courage to open a discussion on the subject of professional fees, which have, through the action of weak-kneed cheap-jack kind of practitioners in nearly every district gradually been getting lower and lower the last ten or fifteen years. It is quite time the profession woke up and attempted to do something in the matter, and I hope that every Veterinary Society will, in the near future, copy the South Durham and North Yorkshire V.M.A., and bring the subject prominently before their respective members.

Of course there cannot be a uniform scale of fees for the whole profession, because some animals are only of a commercial interest, and others of a sentimental value. The latter including cats and dogs are luxuries, and should be treated as such, more especially in districts where the clients are rich and can afford and are willing to pay for skilful services.

I should have thought no prominent firm in the West End of London would have charged such a ridiculous sum as mentioned by Mr. Pope, whose minimum fee for treatment of small animals in his infirmary seems to me very moderate indeed. Perhaps the prominent firm of which he complains only value their services at a low figure. If so it must in time recoil upon them, who will, no doubt, when anything goes amiss with their patients, be treated by their clients as cheap-jacks and people to be avoided. As it seems, according to the facts mentioned by Mr. Pope, their client afterwards became Mr. Pope's.

Some few years ago it was reported in the daily press that a prominent member of the profession stated in a Court of Law that 1/- per diem was a sufficient sum for the keep and treatment of a dog. If this be the charge of a reputed leading light of the profession, how will the smaller fry fare in the question of fees. I consider one should value his services according to his own estimation, certainly not at the lowest of cheap-jacks, cutters, etc.

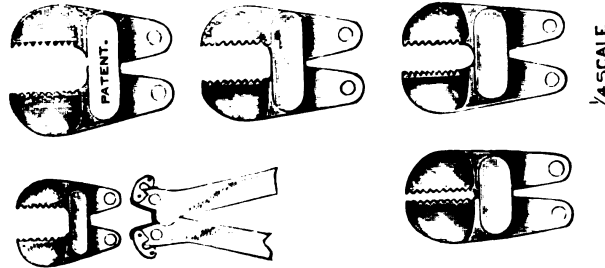

What with well advertised sanatoria run by various people, aided and abetted by practitioners, or even run by members of the profession under different guises one would, at first sight, be led to conclude there would soon be very little left for the majority of canine practitioners. Fortunately, however, the majority of the public well know if they wish for good services they must pay for them. British workmen are more sensible than veterinary surgeons.—Yours truly,

"VIS UNITA FORTIOR."

VETERINARY PARASITOLOGY.

By R. H. SMYTHE, M.R.C.V.S.

Of late years, owing to the increased attention paid to the study of parasitology in our veterinary schools, there has arisen a need in our literature of a text-book, which, although dealing more or less fully with the more common parasites of the domesticated animals, shall yet be concise and of a handy size. It has been the aim of the author to fill the gap with a volume which, while covering the course laid down for the student, shall be at the same time of practical value to the veterinarian as a book of reference. With this end in view, the symptoms produced by the various parasites have been fully described, together with the latest methods of treatment, and, where possible, prescriptions have been inserted.

PRACTICES FOR DISPOSAL

SOUTH EAST COAST. Receipts 1910 £415. Good house, kennels, etc. Very well fitted surgery. Rent £40. Premium £450 and valuation.

SOUTH OF ENGLAND. In present hands 24 years. Receipts last two years average £835 including appointments £70. Convenient house, rent £21, larger house available if preferred. The practice has been worked principally by an assistant who would remain if desired. Premium only £800.

SOUTH COAST PARTNER WANTED. Receipts about £800 per ann. Good house available at moderate rent.

YORKS. Practice principally horse and cattle. Books 1910 show £575. Large convenient house with model stables for seven horses. Well fitted surgery. Rent £75. Practice very compact and easily worked. Premium £375.

NEAR LONDON. Present hands 9 years. Small house rent £30, the practice is principally canine and is easily worked. The returns are stated to be about £400 per ann. Premium one year's purchase.

KENT. High-class mixed practice, returning about £650 per ann. Good premises to be let on lease would be sold. Premium £600.

YORKS. Premium £250. Receipts 1910, £330. Rent £40. Stables and yard almost clear rent. Good agricultural and breeding district. Present hands nearly 20 years. Good house.

LONDON. Thoroughly sound practice, established over 100 years. Receipts about £1200 p.a. Fine house and thoroughly convenient premises. Rent £90. Practice is principally horse. Receipts increasing. Premium one year's purchase.

SOUTH COAST. Old-established Practice for Sale, returning about £550 per annum. Present hands five years. Convenient house, rent moderate. Premium £500.

LONDON. Present hands 30 years. Vendor retiring. Mixed practice. Rent £75. Receipts average £1078. Premium one year's purchase. Strongly recommended.

SEASIDE. Partner Wanted in old-established Practice capable of great increase. Receipts approximate £700. Working expenses low. Good house, rent £60. Premium for half-share £350.

SOUTH OF ENGLAND. Receipts average £650. In present hands 13 years. Usual fees. Good house, three stalled stable, four loose boxes, kennels, cat house, etc. Rent £85. Delightful residential locality. Vendor is well-known to us. Premium £750.

SCOTLAND. General mixed practice returning nearly £700 per annum. Contracts and appointments produce £250 per annum. Practically no night work. Established 30 years, 17 years in present hands. Good house, property of vendor. Rent £60. Premium one year's purchase.

Professional Advertisements.

These will be received up to Thursday morning.
Five lines or under 2/6 (exclusive of heading): for two insertions 4/-; for three 5/-; after three 1/- each.
Each line above five—first insertion 6d; after first 3d.
Average—seven words in a line.

These Advertisements will not be inserted unless prepaid, and if replies are to be received at this office an extra sixpence must be included.

South Africa

VETERINARY Surgeon wanted for South Africa, salary at the rate of £350 rising by annual increments of £15 to £500, contract for 3 years in first instance. Successful candidate to acquire knowledge of Dutch within reasonable time, free passage, half pay from date of embarkation till date of arrival in Cape Town. Selected candidate required to sail by end of September. Applications with copies of testimonials to be in the hands of the High Commissioner for the Union of South Africa, 72 Victoria Street, S.W., by the 19th, August, 1911.

To Veterinary Surgeons

M.R.C.V.S., (1899) wants post as assistant, steady. References furnished on application. Address, 2081 V.R., 20 Fulham Road, London, S.W.

Locum or Assistant

CLASS D student, Vet's son, (Xmas) desires situation. Seen a good deal of practice. Ride and drive. References. Expenses and small remuneration. Address, A. Whitelaw Carter, Vet. Infirmary, Aldershot, Hants.

Locum Tenens

M.R.C.V.S., thoroughly used to country practice and holding testimonials as to ability and general character from many practitioners, is always open to engagement when not actually filling a post. Permanent Address, "Locum," 59 Gascony Avenue, London, N.W.

Wanted

ASSISTANT for mixed practice. Must be able to drive. Apply, giving references and stating salary required. Address, 2082 V.R., 20 Fulham Road, London, S.W.

For Sale

NUCLEUS, London suburb, good opening for energetic man. Address, 2083 V.R., 20 Fulham Road, London, S.W.

To See Practice.

STEADY gentlemanly youth (seen a little practice) ride and drive, passed A & B exams. desires during vacations (or a longer period might be arranged) experience in extensive busy mixed practice. State premium required. Whitehead, M.R.C.V.S., Batley.

Pupil Wanted

VACANCY occurs in an extensive mixed country practice in the Eastern Counties for a gentlemanly youth as pupil. Premium required. Address, 2084 V.R., 20 Fulham Road, London, S.W.

Mallein and Tuberculin

MEMBERS of the Profession may obtain Mallein and Tuberculin on application to the Principal, Royal Veterinary College, Camden Town N.W., on the following terms: in bottles, 6d. per dose. Minimum quantity supplied, two doses. In hermetically sealed tubes, containing one dose each (specially suitable for use abroad) 1s. per dose.

G. H. PICKWELL, M.R.C.V.S.

Locum:

73 Victoria Mansions,
South Lambeth Road, S.W.

HUGH R. SINGLETON, M.R.C.V.S.

Locum Tenens.

Disengaged August 18th,

44 St. Michaels Road,
Bedford.

Locum Tenens

WALTER G. GREEN, M.R.C.V.S.,

c/o Chas. Haywood, Esq., M.R.C.V.S.,
Millstone Lane, Leicester.

Locum Wanted

WANTED locum from August 15th, for a week. Reply with terms, Pawlett, Bootham, York.

Assistant

ASSISTANT wanted in busy London practice (horse and dog), recent graduate preferred. Address, 2085 V.R., 20 Fulham Road, London, S.W.

Assistant

WANTED reliable assistant for busy mixed town and country practice. Apply, giving full particulars. Address, 2086 V.R., 20 Fulham Rd., London, S.W.

As Locum or Assistant

RECENTLY qualified M.R.C.V.S., desires position as above. Excellent testimonials, and good practical experience. No objection to position abroad. Address, 2087 V.R., 20 Fulham Road, London, S.W.

As Locum Tenens

M.R.C.V.S., recently qualified, is open for engagements as above until end of October. Excellent reference of four years pupilage in country practice. Total abstainer. Ride, drive and cycle. Address, "Vet." 4 Marlborough Road, Waterloo, near Liverpool.

To See Practice.

WANTED by class C student to see cattle and horse practice. Would give services in return for board and lodging. Address, B. Sewell, 19 Carlyle Square, Chelsea, S.W.

For Disposal

GOOD practice in charming part of Devon. Price, less than half-a-years takings. Owner going abroad. Address, 2089 V.R., 20 Fulham Road, Loddon, S.W.

All communications respecting advertisements should be addressed to

H. & W. BROWN, 20 Fulham Road, London, S.W.

Tracheotomy Tubes

MISS JONES, successor to F. B. Jones, M.R.C.V.S., still continues to supply the Special Tracheotomy Tubes patented by her late father. Special terms to Veterinary Surgeons. Address, 86 Kimberley Road, Leicester.

For Sale

SMALL practice, no qualified opposition, increasing every year: owner giving up owing to ill-health. Returns about £200: No horse required: genuine. £85 including drugs and instruments. Motor cycle can be had. Address, 2088 V.R., 20 Fulham Rd., London, S.W.

Locum Wanted

FOR country practice in North of Ireland (must be Protestant), from 31st inst. until Sept. 16th, recently qualified man not objected to. Irishman preferred. Apply with copies of references. Address, 2208 V.R., 20 Fulham Road, London, S.W.

Class D Student

DESIRES to see practice until the end of September, has been up for the final and has seen practice. Address, Eason & Son, Ltd., Dublin.

As Locum or Assistant

FINAL year student (29) offers services as above, extensive experience as locum, mixed and dog. Ride and drive, disengaged after September 2nd. Address, S. Woods, c/o M. Bray, M.R.C.V.S., Docking, King's Lynn, Norfolk.

Partner Wanted

IN extensive, old established horse and dog practice on the South Coast. Good contracts, average returns £650 per annum, with room for considerable increase. Address, 1081 V.R., 20 Fulham Road, London, S.W.

Unqualified Assistantship Required

BY young unqualified man, lately assisting in a veterinary practice, town and country. Good horseman and not afraid of work, age 21. Well up in all veterinary work. Moderate salary required. Address 1082 V.R. 20 Fulham Road, London, S.W.

As Assistant or Manager

MR.C.V.S., married, requires permanency as assistant, or to manage branch. First-class all round experience: highest references: sober not afraid of work. Address, 1085 V.R., 20 Fulham Road, London, S.W.

Practice for Disposal

SCOTLAND. Death vacancy. General mixed practice is for immediate disposal, with shoeing forge. Returns £650 per ann. Good introduction will be given. Most suitable for a young practitioner with small capital. Reasonable terms can be arranged. Address, 1083 V.R. 20 Fulham Road, London, S.W.

Open for Engagement

MR.C.V.S., well up in town and country practice, excellent credentials, open for engagement any kind. Good operator. Locum, 79 Millbrook Road, Barrington Road, Brixton, London.

To Veterinary Surgeons

CLASS D student desires situation; has seen practice. Services for board and expenses. Address, "Vet. Student," 11 Warrington Place, Dublin.

Manager Wanted

FOR veterinary practice, large town, India. Salary £500 a year and house rent free, with option to purchase practice. Reply, stating qualifications, age and experience, to Bramall & White, Solicitors, 23 Leadenhall Street, E.C.

Practice Wanted

WANTED, within 100 miles of Manchester or Liverpool, genuine established practice or good nucleus. Immediate settlement. Confidence observed. Address, 1108 V.R., 20 Fulham Road, London, S.W.

For Immediate Disposal

MR.C.V.S., about to take appointment wishes to sell country practice, in good district, Scotland. C.C. appointment. Doing fully £300. Small price for quick sale. Address, 1087 V.R., 20 Fulham Rd, London, S.W.

Wanted

QUALIFIED assistant for suburban practice, state age, height, references and salary required, live out. Address, 1089 V.R., 20 Fulham Road, London, S.W.

Locum Tenens

SON and Brother of V.S. is open to engagement as locum until October, when returning to college. Highest references from well known practitioners. Address, 2507 V.R., 20 Fulham Road, London, S.W.

Wanted

PARTNER with view to succession, in good mixed practice, returning about £500, room for considerable increase, half share £250 clear. Address, 5073 V.R., 20 Fulham Road, London, S.W.

To Veterinary Surgeons

LOCUM, assistant, branch manager, veterinary surgeon desires permanency, sporting, hunting, country practice. Experienced, reliable, practical, hard worker, castrate standing, good obstetrician, 34, single. Excellent references, interview. Address, 5074 V.R. 20 Fulham Road, London, S.W.

For Disposal

DEATH vacancy, Staffordshire, horse and canine practice, situated in centre of town, receipts £250 per ann., could be greatly increased. Good house, and kennels; working expenses small. Good introduction. Reasonable to immediate purchaser. Address, 3075 V.R. 20 Fulham Road, London, S.W.

For Immediate Disposal

YORKS, North Riding. Wanted, reasonable offer. Receipts over £300, good house to go with practice. Rent £12. Good agricultural and breeding district. Present owner 27 years; no opposition; C.C. appointment; introduction given. Address, 5307 V.R., 20 Fulham Road, London, S.W.

Chlorodyne

FOR SALE, a large quantity of Chlorodyne, full strength, B. P. 1885, at 2/- per pound. H. J. Pratt, Wholesale Druggist, Cleckheaton.

Binding

THE PUBLISHERS bind the Annual Volume in Cloth, lettered for 3/6, or Half Roan, cloth sides, 4/6, (uniform with Vols. I. to XXII.) These prices include carriage (parcel post) one way, to country subscribers. Position of Plates is noted in Index.

"MAGNUM" PESSARIES.

(HEWLETT'S)

"Magnum" Pessaries are prepared with a medicated non-oily base which is both effective as a Uterine Antiseptic and of special benefit in Parturition both in Cows and Mares.

A "Magnum" Pessary should be inserted directly after parturition in order to maintain the Uterus in a healthy state. It can be inserted with the greatest ease and will keep the parts in a thoroughly antiseptic condition for a lengthy period.

Alkaline "Magnum" Pessaries have recently been recommended to neutralise excessive acidity of Vaginal secretion.

"Magnum" Pessaries are supplied according to various formulæ as below, and Veterinary Surgeons' own formulæ can be made up as required.

"Magnum" Pessaries.		Doz.	12 doz.	Doz.
	Acid Boric 2 drms.,	4/6	@ 4/-

ROYAL (DICK) VETERINARY COLLEGE, Edinburgh,

Principal:
O. CHARNOCK BRADLEY, M.D., D.Sc., M.R.C.V.S.

89th SESSION.

The only Endowed Veterinary School
in Great Britain.

The Equipment of the College has been strengthened and modernised and the Teaching Facilities greatly increased.

An EXAMINATION in GENERAL KNOWLEDGE for intending Students will be held on 7th, 8th and 9th September.

Next Session commences,
Monday, October 2nd.

Further particulars may be learned on application to

ROBERT ANDERSON, S.S.C., Sec.
37 York Place, Edinburgh.

ROYAL VETERINARY COLLEGE.

Principal and Dean:
Prof. Sir JOHN M'FADYEAN, M.B., B.Sc., M.R.C.V.S.

SESSION 1911-12.

The Winter Session will commence
on Monday, October 2nd,

When the Chair will be taken by

LEONARD BRASSEY, Esq., M.P., and the
INTRODUCTORY ADDRESS delivered by
STEWART STOCKMAN, Esq., M.R.C.V.S.,
Chief Veterinary Officer to the Board of
Agriculture and Fisheries, at 3 p.m.

An Examination in General Knowledge will be held at the ROYAL VETERINARY COLLEGE, CAMDEN TOWN, N.W., by the Educational Institute of Scotland, on 7th, 8th, and 9th of September.

The College Calendar, with full particulars of Fees, Prizes offered, duration of Terms, and other information will be forwarded on application to

RICHARD A. N. POWYS, Secretary,
July, 1911.

VOL. XXIV.

GLANDERS IN LONDON.

The summary of returns under the Diseases of Animals Acts for the week ending July 29th shows that no case of glanders was detected in London during the week. Of course this does not suggest that the disease has been stamped out in the metropolis, but it is strong evidence that the Order of 1897 is being so administered as to ensure success. Before the Order was in force London had some 30 cases a week, and this is the second time that a free bill has been attained.

The long period of latency of the disease is the difficulty in clearing out glanders. Months may pass during which an unsuspected horse may remain infected without any indication of his condition, and then he may develop clinical symptoms and infect other horses. Without mallein these cases might continue the disease for years, but as each clinical case is now followed by a mallein test of the whole stud there is little chance for the escape of infection, and so we may look forward with confidence to the entire suppression of glanders at no distant date in Great Britain. Ireland is already free.

THE V.M.A. OF IRELAND.

From the report of this Association's proceedings which we print this week, it will be seen that Profs. Mettam, Craig, and O'Connor provided the members with material for discussion of quite unusual interest and variety. Four communications from the Dublin teachers were placed before the meeting—all of scientific interest and all having considerable practical bearing upon every day clinical work, while their diversity of subject-matter catered for the needs of all the members. Every practitioner should read the full report; and, whatever his line of practice may be, he will find something of interest and value.

First came a *resumé* of experimental work, some of it performed at the Dublin school, upon the still somewhat debateable question of the fate of fluids in the stomach of ruminants—a subject of incalculable importance in country practice, as was well illustrated by the discussion. Then followed some experiments upon eserine, which do much to discredit the view that that drug is unreliable in its effects upon the normally charged equine intestine. Next came a contribution to the question of canine and feline tuberculosis—a subject which certainly has not yet received the amount of general attention it deserves from practitioners. Finally, Prof. O'Connor presented a report upon the results of the "roaring operation," showing a commendable attention to detail. Not all of the cases reported upon can yet be finally set down as successes or failures;

but the present results distinctly support a view which is now gaining ground, viz., that causes other than paralysis of the arytenoid produce roaring more frequently than has been generally supposed. This may, in one sense, cast undeserved discredit upon the operation, but it certainly limits its usefulness.

The next meeting of the Association will afford a good opportunity of ascertaining the present views of Irish veterinarians regarding roaring and its treatment, for Prof. Craig has promised a paper upon "Roaring and whistling." But it seems evident that all treatment will be more or less unsatisfactory until we can improve our knowledge of the complex pathology of roaring, and our methods of clinical differential diagnosis. An exploratory incision into the larynx is hardly an ideal diagnostic procedure; and there seems to be no other method of determining whether or not arytenoid paralysis exists.

The staff of the Dublin College, however, are doing their share of work upon roaring—and upon other subjects of even greater importance to the practitioner. They presented a portion of it at the meeting under notice, and its value will be widely recognised outside Ireland.

PITFALLS.

It would seem not unreasonable to suggest that the question of the lurking snares and pitfalls that lie privily in wait for the first tottering steps of the veterinary aspirant might with profit constitute a subject for a short course of lectures at our Colleges. In view, moreover, of the early essay into the art of healing made by most keen students, the first year might be chosen as a suitable opportunity for a little light upon the path. Theoretically of course the student is not supposed on the passing of his first examination to have entered upon that stage of his education which would justify him in undertaking any treatment. In point of fact, however, the average student is not slow to avail himself, during a vacation in his own district, of any small prestige that may attach to his being at a Veterinary College, and he is humanly apt to "assume a virtue" if he hath it not. There must be many of us to whom the twinges of a remorseful conscience will testify to the truth of this statement, when, with zeal vastly disproportionate to knowledge, we rushed in like fools "where angels fear to tread." There are, of course, fatalists who say that each man must make his own mistakes and gain thereby his own bitter experience, but though this conclusion is to a slight extent admissible, it is far too pernicious a doctrine to admit unreservedly. To admit this

would be to place empiricism on a lofty pedestal at the foot of which education would clamber in vain. The red flag in the hedge is sufficient evidence of wire to most people; it is only exceptionally that a broken arm or collar bone is necessary to demonstrate its significance. There is no doubt that in the course of College education the majority of our teachers endeavour to point out as they go along the mistakes that are likely to be made, and the course that should be taken to avoid them, but these warnings coming, as they often do, as additional pabulum to a mind already gorged with facts and in a state of mental dyspepsia, are not digested as they should be. If a separate subject could be made it would appear likely that the lessons might be better taken to heart.

And now to take a few illustrations of these pitfalls. The ill-judged poulticing and hot fomentation of a wound in the region of a joint, leading to softening and ultimate septic infection of the joint. The recollection is still sore with me how that I brought about the uselessness of a hundred guinea hunter, that had injured his knee by falling with me in a point-to-point, by these means. Fortunately he was the property of a close and amiable relative. Thinking to effect a speedy cure I instituted a course of poulticing—hot fomentations which were followed in the fullness of time by escape of synovia from the softened capsular ligament, infection, and open joint. This was during my second year.

Another well marked case of error that occurs to me was castration by not over clean ligature leading to schirrus cord and subsequently peritonitis and death.

The opening of a bursal enlargement over the cervical vertebrae leading to infection and fistulous wither.

The opening of a bursal enlargement in front of fetlock (due to rupture the result of contusion), leading to septic infection and death.

The administration of aloes in Pink-eye. In this case the yellow staining of the conjunctiva evoked the diagnosis of "liver out of order." How was the poor tyro to know that this pigment staining is hæmatogenous and not hepatogenous in origin. In this case the result was superpurgation and death.

Puncture firing of a slight spavin leading to penetration of the true hock joint and subsequent septic arthritis.

It is hardly necessary to multiply instances. All of us must be able to recall such mistakes. The epitaph "killed by kindness" might be written over scores of nameless graves, and the murderer has not always been a layman.

"Seeing practice" as a student goes far to place the qualified V.S. above the danger of the simpler errors, but it is sad to contemplate the slaughter of the innocents that have marked his uphill progress. In many cases, too, where the student is seeing practice with a busy V.S. it frequently happens that almost at the beginning of his experience a lad of promise has many fairly responsible cases delegated to him for his sole treatment.

There are many points on which a lecturer might lay great stress. The danger of probes. Even in the most experienced and expert of hands the probe is not always a safe instrument; in the hands of the tyro it becomes a menace. A movement of the animal and in goes the probe, opening up fresh tissues for infection, penetrating synovial capsules, and doing all manner of harm. Then the drenching of animals indiscriminately. The tying up of the head of a pneumonia case while copious libations of fluid and frequently acrid drugs are poured impartially down trachea and oesophagus. The castration of colts through a tiny crooked incision in the scrotum through which the testicle can only be squeezed with difficulty, leaving a dependant pocket admirably suited for the retention of wound discharge. The cauterization of the bleeding spermatic cord stump with *white* hot iron, and the application at the same unsuitable temperature to the docked tail stump.

The mistakes which the tyro makes are not new mistakes. They are the same mistakes over and over again with each succeeding generation. They are not even numerous. They should form a subject, the instruction in which should be so thorough that each student on being questioned would be certain of 75% marks.

WAKEFIELD RAINEY, Capt. A.V.C.

Tempe, Orange Free State.

PARALYSIS IN DOGS.

By HENRY GRAY, M.R.C.V.S.

"W. R. C." in a footnote to a translation from the German on "The Conformation of the Dachshund as a Cause of Paraplegia" questions Jakob's conclusion that long-back breeds are more commonly affected than those having short backs.

Although I cannot accept Jakob's explanation of the causation of paraplegia in Dachshunds, my experience so far as the disease being oftener encountered in long-back dogs absolutely coincides with his.

I have found that nine cases out of ten occur in long-back dogs; nine cases out of ten of these in the Dachshund, and nine cases out of ten in the Dachshund in the fawn variety.

In the fawn variety it seems hereditary. This can be explained by Mendel's Law. In numerous instances I have found several members of the same strain attacked. Indeed, I have seen brother and sister, mother and son, etc., attacked with paraplegia at the same time.

I consider there exists in this breed a liability to a rheumatic diathesis, if I may be allowed to use such an expression. Time after time I have seen rheumatic symptoms precede the paraplegia, which is a pressure paralysis, brought about by a thickening of the spinal dura mater. If the rheumatic process attacks the dura mater in close proximity to the sensory roots of the spinal nerves, great agony is experienced (*vide* a paper by me on this subject in *The Veterinary Record*, July 16th, 1904). If, however, only the dura mater not in the vicinity

of the spinal nerves be affected, paralysis without any agony is encountered.

These cases usually respond to the treatment generally recommended for rheumatism. Aspirin (or acid acet. salicyl.) or sodii salicylas, and after a time potassium iodide are the best agents, either by the mouth or by ionization. Strychnine, Nuxvomica, or electricity are useless; they generally make paraplegia due to pressure worse or incurable.

The second paragraph of "W. R. C." translation seems to me far-fetched if not contrary to fact. Perhaps "W. R. C." will give your readers *his* reasons and *his* facts for doubting the greater prevalence of paraplegia in long-back dogs than in the short-back breeds?

NEW SKIN DISEASES IN THE DOG.

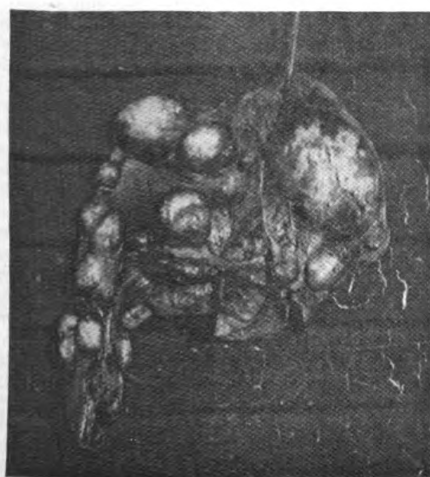

By HENRY GRAY, M.R.C.V.S.

On p. 72 of *The Veterinary Record*, July 29th, 1911, Mr. Livesey is reported to have stated at the last meeting of the Central Veterinary Society that he had encountered, during the last ten or twelve years, several cases of a peculiar skin disease in the dog, which had not been described or named. I believe this is contrary to fact. On reading Mr. Livesey's description, as reported, I consider his cases were none other than follicular mange, plus the bacillus of necrosis.

It is not always easy to find the follicle mite unless true yellowish pustules are present. In one case in my mind's eye three months elapsed before I could confirm my diagnosis of follicular mange by finding the follicle mite, and then only in one isolated pustule.

Tincture of iodine, biniodide of mercury ointment, mercurial ointment, pure creolin, or nitrate of silver have usually, in my hands, brought me success in such cases as described by Mr. Livesey.

TUBERCULOSIS IN THE HORSE.

Subject. Cart horse, six years old.

History. Owner paid 45 guineas for horse three months previous, and said it had gradually wasted away. I was asked to destroy the animal and make a post-mortem, but on arrival at farm found the animal had been dead some six hours.

Post-mortem. The whole of the mesenteric glands, right kidney, spleen, and right tubercle (the subject was a monorchid) showed characteristic signs of caseation and calcification, and were enormously enlarged, with the exception of the testicle which was atrophied and solid. The spleen weighed over twenty-two pounds.

JAMES M. RICHARDSON, M.R.C.V.S.

Deal.

VETERINARY MEDICAL ASSOCIATION OF IRELAND.

(Concluded from p. 96.)

SOME NOTES ON THE PASSAGE OF FLUIDS THROUGH THE STOMACHS OF RUMINANTS.

By Prof. CRAIG, M.R.C.V.S.

To the classical researches of Flourens and Colin we are indebted for our present knowledge of the physiology of the stomachs of ruminants. Both these investigators showed beyond doubt that all the solid materials pass after the first deglutition from the oesophagus only into the reticulum and the anterior portion of the rumen. From their experiments they also concluded that fluids and semi-solid material were carried in small proportion from the oesophagus directly through the oesophageal groove to the omasum and thence to the abomasum. The experiment on which they based their conclusions were the following:—

1. Flourens fed a sheep on some roots reduced to a fine pulp, and then immediately afterwards destroyed the animal and made a post-mortem examination. He found the pulped roots in large proportion in the rumen and reticulum, but also in appreciable quantity in the omasum and abomasum.

2. He also made a fistula in connection with each of the four stomachs and found that fluid escaped simultaneously from these openings whenever the ruminant was allowed or forced to drink some liquid.

3. Colin made a large fistula into the rumen in the left flank of an ox. In order to ascertain where the liquids passed from the oesophagus he inserted his hand through the fistula into the rumen as far as the oesophageal opening. He found that when the animal drank water that the latter entered in greater part into the reticulum and then flowed over into the rumen. Placing his finger in contact with the lips of the oesophageal groove he found them lightly drawn together, and felt a very small quantity of fluid trickle directly through the groove from the oesophagus into the omasum. This experiment he repeated in several oxen with the same result.

The chief objections to the conclusions drawn from these experiments are: Nos. 1 and 2 do not show that any fluids pass into the third and fourth stomachs through the oesophageal groove without mixing with the contents of the rumen and reticulum. To No. 3 it may be objected that the manipulation altered the normal physiological function of the stomachs and of the oesophageal groove.

Investigations in later years have been made with water tinted with some colouring agent, such as magenta

or fuchsin. These fluids have been administered in various ways; in drench, by probang, and with the animal standing or placed on its haunches and the head held back. Immediately after the water was administered the animal was killed and the contents of the stomachs examined.

Vryburg administered two or three litres of water, deeply coloured with fuchsin, by a stomach pump to four adult oxen. The drenching was carried out with the animals in the standing position and the long axis of the head kept horizontal. To two heifers at the Royal Veterinary College of Ireland half a gallon of water, deeply coloured with fuchsin, was given with the ordinary drenching horn; and to a bullock a similar amount of coloured water was administered by probang. A two-year-old bullock was first allowed a bucket of water and then drenched with two quarts of water coloured with magenta. A goat was given a drench of half a pint of water coloured with magenta. During drenching the latter animal was placed on its haunches and the head held back. The animals were destroyed almost immediately after the material was administered and an examination made of the stomachs. In all cases the colouring agent was found only in the rumen and the reticulum; not a trace had penetrated into the omasum and abomasum. The stain had diffused through the contents of the reticulum, but in the rumen it was present only in the solid food near the walls of the organ.

It might be objected to these experiments that they do not represent what takes place when the ruminant drinks voluntarily of water or the other fluids. At least, however, they show what occurs when medicinal or other agents are given in the form of a drench. These agents are diluted by the contents of the rumen and reticulum before they reach the omasum and abomasum.

PASSAGE OF FLUIDS FROM THE FIRST TWO STOMACHS INTO THE OMASUM AND ABOMASUM.

After a variable period the fluids pass from the rumen and reticulum into the third and fourth stomachs, probably by way of the opening in the reticulum. Vryburg allowed a cow to drink about a litre of coloured water and then destroyed it half an hour afterwards. He found the greater part of the fluid in the rumen, but a small quantity had entered the third stomach and stained the upper portion of the leaves of this compartment. The same result was also obtained on killing a heifer which had been given two litres of coloured water by means of an irrigator, half an hour previously. Three other adult cattle were destroyed, seven, eight, and ten hours after the administration of fuchsin solution. In the first case a little of the coloured solution had penetrated into the third stomach; in the second case the contents of the third and fourth stomachs were stained red, but the pylorus was not coloured; in the third case a small quantity of fuchsin had reached the pylorus and entered the duodenum. At the R.V.C.I. a goat was drenched with half a pint of water coloured with magenta and containing ten grains of strychnine, and died twenty-five minutes afterwards. The colouring matter was found in the rumen, reticulum, omasum, and at the entrance to the abomasum.

ABSORPTION FROM THE STOMACHS OF RUMINANTS.

The mucous membrane of the first three stomachs is similar to that of the mouth. The epithelium is thick, squamous and stratified, and not well adapted for the purposes of absorption. The fourth stomach is the true stomach of the ox. In the last experiment in the goat, symptoms of strychnine poisoning appeared in about twenty minutes after administration. Probably in that time some of the material had reached the abomasum and was absorbed.

SECRECTIONS FROM THE STOMACHS OF RUMINANTS.

I have examined numerous sections of the walls of the first three stomachs and have never seen any glands in them. It is said that a few small mucous glands are present in certain portions of the rumen. These glands, if present, cannot however have much effect in increasing the fluid condition of the contents or lubricating their passage. The consistence of the ingesta depends upon the amount of fluid taken in by the mouth as such, or with food, and of the saliva swallowed.

PRACTICAL DEDUCTIONS.

1. Since all fluids taken in by the mouth must be diluted by the contents of the rumen and reticulum, this dilution may interfere with the action of various medicinal agents in certain cases. This may account for the unsatisfactory results obtained in the treatment of parasitic abomasitis. It might, therefore, be advantageous in these instances to inject the vermicides directly into the abomasum through the abdominal wall. The guide line for this operation is the line of right asternal costal cartilages. The abomasum may be punctured in the ox immediately behind this line at any point within a foot of the xiphoid cartilage of the sternum.

2. Where the contents of the first three stomachs are abnormally dry, they may be softened, chiefly by water taken in by the mouth or by increasing the amount of saliva secreted and swallowed. The removal of the ingesta is effected by the muscular contractions of their walls. Purgatives, such as magnesium sulphate act for the most part on the intestines. They stimulate the passage of fluids into the lumen of the bowel by increasing osmosis, and the secretion of the intestinal glands. The mechanical distension of the gut with fluid provokes slight peristalsis. This increased peristalsis may be transmitted thence to the first three stomachs, and perhaps some of the fluid in the bowel may be carried forward to dilute the contents of the omasum, reticulum, and rumen. Stimulants to the muscle fibres are of the greatest service in producing the desired effect upon these organs. Thus it is that such agents as the Strychnine preparations, Nux vomica, and the Ammonia compounds prove very useful adjuncts to laxatives in cattle. It may be truly said that the combination of stimulants with a moderate dose of laxative will effect what a strong purgative of, say, Epsom salts, fails to produce upon the stomachs of ruminants.

DISCUSSION.

Mr. P. J. HOWARD wished to congratulate Prof. Craig and Prof. Mettam on the fact that they had begun to pay attention to perhaps one of the most important matters that concerned the veterinary profession in this country. He did not think they had a lot to learn about digestion in ruminants. He would like Prof. Craig to remember that he must be careful in the deductions he drew from experiments on the sheep as compared with what went on in the ox. Though they were both ruminants in every sense and much alike in the arrangement of the stomach they were very different in the question of their natural lives. (Hear, hear.) It was a common thing to find sheep in various parts of Ireland that had never been known to have a drink of water, and they did well, and were perfectly healthy, whereas in the big cattle rearing districts it was of especial importance to have a sufficient supply of water. His own experience had always led him to think that in giving fluids to the ox that the fluids went directly only to the rumen and reticulum, and probably a great proportion of the fluid remained in the reticulum. It was common in the West to have a good deal of treatment of murrain in cattle, i.e., where they got severe constipation, and on some of these occasions they got ample

evidence that it would be an absolute impossibility for anything to pass through the abomasum, even if they used a force pump. The part would be as much like a football as anything, and it was quite common that this should be going on for a week before it was detected. He believed himself that nothing passed from the reticulum or rumen unless by the process of chewing the cud. He wished to ask whether, in these experiments, the animals had been induced to go through the ordinary process of chewing the cud before they were killed. Even the fluid contents of both stomach pass on in that way. He believed this from his experience of post-mortems on beasts that had died from murrain, in which they got the contents of the rumen and reticulum absolutely fluid, and the omasum parched. He hoped Prof. Craig and Prof. Mettam would help them to arrive at some better knowledge of these matters than they at present possessed. He wished to offer his thanks for the very interesting paper. (Hear, hear.)

Mr. McKENNY said these experiments related to fluids. The natural process with the solids would be different, and the liquid experiments to a considerable extent would give them no information as to the solids. He would agree with Mr. Howard as regards the liquids. For many years past he had made a practice, when an animal was constipated, of giving after every dose of medicine three gallons of warm water—drench them with it, they could not get them to drink water sufficiently warm—and had had wonderful success by the treatment. He thought that success had been explained by the fluid experiments. For almost every disease in the ox he ordered that the hot water should be given two hours after the dose of medicine whatever it may be, and to have this carried out he explained to the owner the necessity of it by saying the medicine would do absolute harm if it was not diluted afterwards with water. But his reason was to soften the contents in the omasum. That was his idea, and he believed that the fluids did pass into the omasum. He would like some experiments as to the solids. It was a subject well worth bringing up, and had been most interestingly dealt with, and could be turned to practical good. (Hear, hear.)

Mr. A. WATSON remarked that one might have feared from the way the paper was titled that it would be most highly scientific, but on the contrary Prof. Craig had handled his subject in such a way as to make it understandable to the man in the street. Certainly similar thoughts occurred to him as occurred to Mr. Howard as to the contrast between sheep and cattle, for he thought he was right in saying that sheep as a matter of fact do not drink water. It was a symptom that they were unwell when they took to water. In their usual health they would be content with the amount of moisture in the pasture. He thought the matter of murrain was one that had a very real interest for every practitioner. Anyone who had treated murrain must be aware that it was futile pour purgatives into the cattle attacked, and how even with enormous quantities of purgatives they did not respond. Before he left practice he adopted the course of giving along with the purgative tincture of Nux vomica and a good dose of whiskey, in order to get the muscular coats of the stomach to respond, for in these cases they had undoubtedly paralysis of the muscular coats of the stomach. As meat inspector at the abattoir he came across a number of animals sent in to be slaughtered, supposed to be suffering from murrain. The ordinary symptoms looked for in murrain was the condition of the third stomach. If that was dry and hard it was supposed to be murrain, and that no quantity of purgative medicine would remove the obstruction whilst the paralysis existed, so they ought to combine nerve tonics and stimulants.

Another point was the question of absorption from the

first two stomachs. If he took Prof. Craig aright, he seemed to think there was a very small absorption. The area was so big that they could certainly fancy there would be considerable absorption. He might be wrong, but he thought there ought to be less absorption from the rectum than from the rumen. ("No, no.") Why he said so was because in the case of yew tree poisoning, the leaves and small branches were only found in the rumen, and yet death occurred from the poisonous alkaloids. As to the characteristic post-mortem appearances supporting the diagnosis of the pre-existence of murrain, it was a common mistake with practitioners to think because the mucous coats were adherent to the ingesta that murrain must have existed. They never paid any regard to the time the ingesta was left in the stomach before the post-mortem. If it was some time it would become adherent, and it was not a symptom of pre-existing disease at all. (App.)

Mr. WILKINSON: Do you think those changes occur after death?

Mr. WATSON: Yes.

The PRESIDENT: It is uncertain, pure and simple.

Mr. HOWARD: It will occur in two or three hours.

The PRESIDENT: Yes.

Mr. WATSON, in conclusion, acknowledged his generous appreciation of the great service Prof. Craig and Prof. Mettam had rendered them by bringing forward that most important subject in that delightful manner.

Mr. L. M. MAGEE thought that in order to have an accurate and natural test they would have to allow the beast to drink of his own free will, and then slaughter immediately afterwards. He had no data to go on, but he was of the opinion that if, for instance, a bullock was very thirsty and they gave him a couple of buckets of water, a considerable amount of it would pass directly through the omasum into the abomasum. If all the water flowed into the rumen he would not derive benefit from it, or have his thirst quenched, for a considerable time, as that stomach had practically no absorptive powers. That could hardly be said to be a good provision of nature.

Although the omasum or "book" might be packed with food, water could still pass through that compartment by means of the groove which runs beneath the free edges of the leaves, and which forms a direct path from the reticulum to the omasum for fluid and finely divided food. When the layman made a post-mortem examination and found the food between the leaves dry, he naturally concluded that it was the cause of the animal's death, whereas in reality it was a normal condition. There were two conditions generally referred to as murrain—dry, and red murrain. The one under consideration was dry murrain. He thought they did not resort sufficiently to the administration of medicine by the hypodermic syringe. They would get better results if they did.

With regard to Mr. Watson's remarks as to absorption, Mr. Magee said the rumen was simply a reservoir and there was practically no absorption from it. As proof of the wonderful powers of absorption of the small bowel he called to mind when he was a pupil with Mr. McKenny, a case of tetanus that for over a month took no nourishment by the mouth except water, and received all its food per rectum, and when the horse recovered he had lost very little of his condition.

Lieut.-Col. STEEL did not think the question of absorption from the rectum admitted of any doubt. He instanced a case in which food was given for six months entirely by injection. That settled the matter at once.

Prof. CRAIG thanked the members for the reception given to the paper. Replying to points raised, he said Mr. Howard in his remarks apparently thought they were paying more attention to the sheep than to the ox.

Mr. HOWARD: Not at all. I simply threw out the

suggestion that you could not be safe in drawing conclusions as regards the ox from experiments on the sheep.

Prof. CRAIG said most of the deductions that were made were obtained from experiments on the ox. Mr. Howard had said he thought unless rumination occurred no fluid, or very little fluid, would pass from the rumen or reticulum into the omasum or abomasum. The experiments he had given were on animals which did not ruminate during the time of experiments, and in the ox, where a sufficient interval had elapsed before the animals were destroyed the fluids had passed from the first two stomachs into the third and fourth. Mr. Magee made a criticism with reference to what would occur if the fluids were taken up voluntarily by the ox. He had just read an experiment with reference to that particular point. It was made by Vryburg, whose observations agreed with their own. The reason he did not refer to it in the first instance was that half an hour had elapsed before the animal was destroyed. The result was—this was his (Prof. Craig's) explanation—that the fluids had passed just as in the case where the animal was drenched, but in the interval after the fluids had been taken in, and before death some had passed from the reticulum into the omasum. If one would judge from that experiment alone one would take it that in natural circumstances the same route was taken, no matter whether the fluids were taken voluntarily or given in the form of a drench. In one case he gave a bucket of water to the animal, and then drenched the animal with the fluid, and they passed, just as in the first instance, into the rumen and reticulum. Mr. Howard referred to the condition of the omasum found commonly in cases of murrain—but also in normal cases—and said that the condition of the omasum was such that no fluids could pass. There was, however, a distinct open run on the floor of the omasum.

Mr. HOWARD: That brings out what I said, that what passes into the omasum goes along that vessel and not by absorption.

Prof. CRAIG said the opinion he held was that murrain was frequently due to some defect in the muscular action of the stomachs of the ox, and that this defect was overcome by the action of stimulants. With regard to the question of absorption from the stomachs of ruminants, the only evidence he could bring forward was that stated in the paper in referring to the nature of the epithelium and the experiment with strychnine. In explanation of what took place in yew poisoning, he considered that sufficient time elapsed between ingestion and death to allow of the passage of the toxic materials from the rumen and reticulum into the abomasum, there to be absorbed. If these stomachs were examined after death it would be found that a large quantity of yew was present in the rumen and reticulum. This must have taken a considerable time to devour. This interval would permit of the solution of some of the active agents in these stomachs and their passage to the omasum and abomasum, where they would be absorbed. Then the symptoms of poisoning would be set up and death result.

NOTES ON THE ACTION OF ESERINE.

By Prof. A. E. METTAM, M.R.C.V.S.

The objects of the experiments was to determine the effects of eserine upon the contents of the alimentary tube when the latter was not surcharged with ingesta; or, to put it differently, to ascertain if eserine would act upon the alimentary tube and its contents as it is known to act in cases of stoppage or obstruction. It has been stated that eserine only exerts its effects when the bowel is filled with ingesta, and that when the tube is relatively empty its effects are little evident or may be entirely wanting.

Messrs. Parke, Davis and Co. kindly supplied me with physostigmine salicylate for purposes of the experiments.

First experiment.—Black, aged gelding, received two grains of physostigmine salicylate into the jugular vein at 9.55 a.m.

The animal defæcated at 9.57 apparently a normal motion.

Fæces was also passed at 10.26 a.m., 11.2 a.m., and 11.35 a.m.

Flatus was passed at 11.45 a.m., but there was no pain and no straining.

Fæces passed at 11.51 a.m., 12.0 noon, the fæces being soft and pultaceous. There never was any sign of inconvenience or uneasiness or any other indication of colic.

The animal was killed at this time for dissection.

Chestnut gelding, aged, received $2\frac{1}{2}$ grains of physostigmine salicylate into the jugular vein at 10.8 a.m. The animal at no time showed any pain.

Fæces was passed at 11.13 a.m.

" " " 11.42 "

" " " 11.56 "

" " " 12.10 afternoon (liquid)

12.30 p.m. the fæces were softened. The animal was uneasy and strained occasionally as if it had had an enema.

Action of the physostigmine passed off about 1 p.m., the animal becoming quiet, and no more fæces were passed while the animal was under observation.

Both animals chumped the jaws, the movements commencing about half an hour after receiving the alkaloid. There was no salivation, save perhaps in the black gelding, where there was possibly some extra secretion of saliva, but nothing of consequence beyond merely mentioning the fact.

Brown gelding, aged, received into the jugular vein three grains of physostigmine salicylate in 12 c.c. of water. The animal had a well marked jugular pulse. The injection was made at 1 o'clock (afternoon). Immediately afterwards the animal appeared dazed, extended the head, and crouched. He then fell forwards and struggled violently. He was much distressed. There was violent muscular spasms and a hippocentric grin. The pupils were widely dilated. The animal lay for some time, occasionally struggling, and had violent paroxysms of spasms. At 1.30 there was much tenesmus and passing of softened fæces; 1.32 more fluid passed; 1.34 fæces passed; 1.36 straining with passage of liquid fæces; 1.38 straining and passage of fæces; 1.40 straining; 1.41 straining and passage of liquid fæces; 1.43 ditto; 1.44 tenesmus; 1.46 ditto, fæces passed; 1.50 great quantity of egesta passed, more than all previous motions collected; 1.54 violent straining, passage of liquid fæces; 1.55 ditto; 1.58 great evacuation of liquid fæces; 1.59 involuntary flow of liquid fæces; 2.0 got up and passed liquid fæces; 2.1 large quantity of liquid fæces; 2.5 straining; 2.6 ditto; 2.7 ditto, and passage of liquid fæces; 2.8 colicky pains, flatus and fluid; 2.9, 2.10, 2.14, 2.16 straining, passage of liquid fæces, colic; 2.18 flatus; 2.19 very violent straining and passage of much fluid; 2.21 ditto; 2.22 straining, 2.24 ditto and flatus passed.

Straining continued, but less frequently, till 3 p.m., pulse at this time 50. The animal was somewhat dull, but there was no pain or muscular spasms.

Four days later the animal received at 11.35 a.m. 1 grain of physostigmine salicylate dissolved in boiled water. Injection was made as previously into the jugular vein. The object of the second experiment with a smaller dose of the drug was to decide if the excessive action of the previous dose was due to any idiosyncrasy, or perhaps to the heart lesion.

Animal immediately became uneasy, and there were violent muscular spasms of abdominal wall. Attempts to evacuate occurred within first five minutes, and the animal strained like a mare at parturition. There was

dilatation of the pupil within ten minutes. The animal made preparation to lie down but refrained (colic). It continued to strain and groan, and passed flatus. There was also regurgitation of air into the bowel. The animal defecated at least eight times during the half hour following the injection, and the faeces became more and more softened, unformed, and like cow dung. The spasms after this became less and less frequent, and eventually passed off. At 3 p.m. the animal was in its usual health. The jugular pulse noticed at the first experiment was still present.

On the same day, and at the same time, the chestnut gelding which got $2\frac{1}{2}$ grains into the jugular vein as above mentioned, also received 1 grain of the physostigmine dissolved in boiled water into the jugular vein. The animal became uneasy, but not nearly so much so as the brown gelding, and defecated twice soon after receiving the dose. There was again champing of the jaws. Faeces were passed on three occasions within twenty minutes after the injection. There was no groaning, no tenesmus as in the brown gelding. Faeces passed were firm. The animal half an hour later was apparently in its usual health. No dilatation of the pupil noticed. At 3 p.m. animal found standing to all appearances perfectly normal, with a soft unformed motion behind him.

The conclusions are that physostigmine acts upon the bowel (muscular coats) even when there is no great excess of ingesta.

Physostigmine acts upon the heart, and that it is better when using this alkaloid to examine the state of the heart, this is indicated by the alarming symptoms exhibited by the brown gelding when it received one grain into the venous system. It is interesting to compare the result of this injection with the effect upon the chestnut gelding. The dilatation of the pupil is interesting and unusual.

Physostigmine, when applied locally, causes contraction of the pupil; atropine, its antagonistic, causing dilatation.

DISCUSSION.

Mr. L. M. MAGEE considered the notes were a valuable contribution to veterinary literature. For the last eight years he had a good deal of experience with eserine and he was convinced that it was a drug that was not used half enough, especially in cases of colic from impaction. Of course, there were many conditions that influenced the advisability of its administration. To his mind it was simply criminal to think that colic, no matter what its cause, could always be treated on the same lines. The custom of sending large bottles of colic medicine, composed mostly of sedatives, to their clients for emergencies should be condemned. The causes of colic were very numerous and their diagnosis often extremely difficult, and one was sometimes justified in waiting half an hour or more before deciding on a line of treatment. Once he had made up his mind that the case was a suitable one he did not hesitate to administer eserine or arecoline. The thing to pay attention to was the pulse. If the pulse was weak these drugs were contra-indicated. For several years he had been a disciple of Caulton Reeks, and was a firm believer in the stimulant treatment of colic. He was very proud of his little veterinary library, but the two books he valued most were Reeks' "Common Colics of the Horse," and "Diseases of the Horse's Foot" by the same gifted author.

Mr. McKENNY asked Mr. Magee which of the two he really believed in—waiting and carefully diagnosing the case and adopting treatment accordingly, or adopting Mr. Reeks' treatment of stimulants? Personally he (Mr. McKenny) used stimulants. He first diagnosed his case and treated it accordingly, but he always used stimulants.

Mr. HOWARD said he had been much disappointed in the action of eserine where you had absolute impaction, and he confined his use of it to where there was flatulence to be got rid of.

Mr. W. H. WILKINSON said he had made considerable use of eserine, and he agreed with Mr. Magee it was one of the most valuable drugs that they had, but it wanted to be used with extreme care. He had stopped giving even two grain doses. He preferred to give a grain now, and one at an hour's time, otherwise they got alarming symptoms.

TUBERCULOUS PLEURISY IN A DOG.

By Profs. CRAIG, METTAM, and O'CONNOR.

The Subject was a mongrel collie dog about 4 or 5 years old.

The History given was that the animal was noticed a few days previously to be affected with dyspnoea, and that the distress in breathing was increasing.

The Symptoms shown when the patient was brought to the College on the 17th January last were the following. The head was stretched out, the mouth kept continually open, the saliva escaping in strings from the angles. The respirations were very much distressed and numbered about 40 per minute. This distress was greatly increased by movement and manipulation. The condition of the dog was very poor and he was not inclined to take any food. He coughed occasionally and there was a slight yellowish discharge from the nose. The pulse was 120, the mucous membranes were slightly injected, the temperature 104°. No lung sounds could be heard on auscultation of the right side of the chest, crepitation or crackling sounds were heard on the left side, especially near the lower border.

The treatment consisted in the application of a stimulating liniment to the chest wall and a cotton wool bandage, and the exhibition of stimulant and internal antiseptics including quinine sulphate, digitalis, and nuxvomica. Nourishing food was recommended, but the dog refused nearly everything that was recommended. Antiseptic inhalations were also given. The treatment was kept up for a fortnight, but the animal became gradually worse. The temperature came down to 102°F. Emaciation was very pronounced. He died on the 2nd February, and a post-mortem examination was made 10 hours after death. On opening the chest, a light yellowish limpid transparent liquid escaped from the right pleural sac. This was estimated at about 3 pints. The pleura was thickened and presented numerous granulations on the costal portion, especially over the intercostal spaces. The right lung appeared as a small knob at the upper portion of the right pleural sac. It was not one-third the size of the left lung. It was closely adherent to the parietal pleura along its upper border and throughout the inner surface. The lung was collapsed, solid, bright red on section, and sank in water.

The left lung was emphysematous along its lower border and in its spiral lobe. The outer surface presented a large scar-like thickening of the pleura. The heart was very muscular. All the other organs were free from naked eye lesions. Some of the exudate from the left pleural sac was centrifugalised and films were made from the sediment for microscopic examination. Numerous endothelial cells and lymphocytes were present in the films. Several round and fast bodies were found, some inside the cells and a very few tubercle bacilli discovered after a very careful search.

The chief interest in this case lies in the absence of any tuberculous lesions, save pleurisy with effusion.

The second case was that of a foxterrier about four years old received into the College Clinic by Professor O'Connor. The dog had been in possession of the owner for two years, and according to his statement had been in good health apparently until a week before.

Examination of the patient showed him to be in a serious condition, indeed in a state of collapse. The temperature was 99 F. Diagnosis made was pleurisy and pneumonia of the left side. The animal died shortly after admission.

Post-mortem examination. The left pleural sac was filled with fluid clear and yellowish in colour. The left lung was collapsed and firm. Cavities were present in the lung, such as would contain a pea, and these cavities contained pus in which acid-fast bacilli were demonstrated in clumps. Large areas of the lung substances were necrosed, refused to stain in sections though plenty of bacilli could be demonstrated in practically pure culture. On the surface of the pleura was an exudate, and there were tubercular granulations low, flat, and yellowish in colour. The pericardium was adherent to the heart, but fluid was absent from the pericardium. An emulsion was made from the lung and inoculated into a guinea-pig which developed tuberculosis.

These two cases illustrate a by no means uncommon condition in both dogs and cats. From the post-mortem findings infection must have been present for some time, and yet the history obtained does not indicate that the owners noticed anything seriously wrong until just prior to the animal being brought into the clinic. Another interesting point is the excessive amount of fluid present in the pleural sac and the remarkable collapse of the lung, next the absence of lesions usually associated with tuberculosis. In the second case the condition of the pleura suggested tuberculosis, and the condition of the lung strengthened that opinion, but nevertheless this case was not one which conformed to the classical description of tuberculosis in the lower animals. A further interesting fact is the absence of lesions in other viscera. I have noticed for a long time the great tendency for tuberculous lesions in the lungs of carnivora to soften and break down and to give rise to the formation of cavities. The size of these cavities of course varies but they invariably contain a quantity of glassy pus, often extremely rich in acid-fast bacilli.

I have observed this condition not only in dogs and cats but also in the larger carnivora of the Zoo, the lion, leopard etc. In the first case we were convinced that we had a case of tubercle, but it was only after centrifugalising the fluid and making films of the precipitate and staining that an absolute diagnosis could be made. As it has been remarked, the bacilli were few and far between, but they were observed in phagocytes.

It is very probable that a very large percentage of cases of pleurisy both in dogs and cats are due to tubercular infection, and that a very close search is necessary before the organism may be found. It is not easy further to say where the organism has gained entrance, though it is very probable (I am aware that many will not agree) that the infection is through the alimentary tract. I have in remembrance a post-mortem examination I made upon a cat. It had been coughing for some time, and on examination it was found to be very thin. It was a Persian, and the great and rapid loss of condition had not been suspected. A very remarkable one-sided pleurisy was found, with a collapsed lung containing small cavities containing pus, with numerous tubercle bacilli present. A prolonged examination of the other viscera revealed a softened caseous centre in a mesenteric gland, which was judged to be earlier than the lung lesions and as indicating that infection had occurred through the alimentary tract. In this case contamination from a human source must be excluded, and infection by inhalation as quite impossible. Nor is it at all possible that infection occurred through the respiratory passages in the larger carnivora already mentioned—they are housed separately, they are not in contact with man, and infection is only possible through the alimentary tract. The same may be said of tuber-

culosis in the raccoon, in which animal I have seen very extensive tuberculosis of the lungs with little evidence of infection in other viscera. I believe that the evidence for infection by inhalation among the lower animals is insufficient, and I am satisfied from the very numerous cases of tuberculosis I have seen in very many species of animals that infection by the alimentary tract is the rule.

DISCUSSION.

The PRESIDENT said the interesting point in this subject was that in many cases of pleurisy they got in dogs tuberculosis was not suspected. There was nothing to lead one to think there was tubercle. He was convinced that a large number were tubercle, and he would be very glad if members when they came across cases of pleurisy would bottle some of the fluid and send it to him. Dogs and cats were brought into such close relation with human beings that they must make as rapid diagnosis of tubercle as possible. That was the reason they brought the matter forward. Tuberculosis was extremely common in dogs, much more common than many of them imagined.

Mr. McKENNY said there was another view that could be taken of this, and that is, if an animal died and it could be found to have tubercle bacilli could that dog be said to have died from tuberculosis? Could the dog not die from pleurisy? As regards the facts produced it appeared to him it could not be said that what the animal suffered from was tuberculosis. It was only that tubercle bacilli were found in an animal that died from pleurisy.

The PRESIDENT: The point is whether tubercle bacillus was the cause of the pleurisy.

Mr. McKENNY said he very much valued the information derived from the study of bacteriology, but he considered that the bacteriologist who merely formed opinions relative to disease from microscopic examinations retarded the practical importance of the subject. The fact that a certain bacteria existed in an animal does not establish that if the animal died the bacillus was the cause of death. For example—suppose an animal meets with an accident, say fracture of the skull, and dies from same, but on post-mortem examination it was found that it had tuberculosis, surely it would be absurd to state that because on microscopical examination tuberculosis bacilli were found, that it was the cause of death, and in the case cited, the link between the pleurisy from which the animal died, and the small quantity of bacilli, resembling those of tuberculosis which on careful examination were revealed, should warrant the definite conclusion that this exceptional case as described was one of pleuretic tuberculosis. Of course the case was one worth recording, and Mr. McKenny felt indebted to Prof. Craig for having reported it, as no doubt it was of much interest and probably, taken with other similar cases, would be of practical use, but it would be premature and unwise to form any definite opinion as to the cause of the pleurisy in this case.

Mr. MAGEE thought the point Mr. McKenny was making was whether it was a mixed infection.

Prof. CRAIG: There was nothing but tubercle bacilli.

Mr. McKENNY: Am I to understand that if you have a dog suffering from pleurisy, and you find tubercle bacilli, it is that which has caused the pleurisy.

The PRESIDENT: That is the inference. Tubercle bacillus as a cause of pleurisy is more frequent than people imagine. In most cases of pleurisy the cause is not known. We say that the tubercle bacillus is more frequently the cause than is imagined. In cases we have looked into we have found tubercle bacilli.

REPORT ON CASES OF "ROARERS."

Prof. O'CONNOR presented the following report on cases of "roarers" operated on before members of the Association.

No. 1. Aged chestnut gelding, a splendid hunter, a loud roarer. Had a tube in his trachea and it was in consequence of this tube "becoming troublesome" that the owner had him operated upon for roaring. The tube was removed at the time of operation. On opening the larynx the left arytenoid was seen to be completely paralysed. The left ventricle only was stripped.

Result. Stenosis of the trachea occurred when tracheotomy had been performed causing dyspnoea, and the owner had the horse destroyed.

No. 2. Aged brown gelding, a good hunter, a distinct roarer. Left arytenoid completely paralysed. Left ventricle only stripped.

Result. A complete success. Only a faint noise can be heard when quite close to the animal during a gallop, whereas prior to the operation the roaring could be heard at a long distance.

No. 3. A 5-year-old hunter, making a noise. Left arytenoid paralysed. Left ventricle stripped.

Result. Operation successful. Hunts and stays well, only making a slight noise when starting to gallop.

No. 4. A 4-year-old brown thoroughbred stallion making a noise. Both arytenoids moved equally but, it was thought, more slowly than normal. Both ventricles were stripped.

Result. Not improved two months after the operation, when he was sold and lost sight of.

No. 5. Bay gelding making a noise, left arytenoid moving feebly. Stripped the left ventricle.

Result. The horse, I was informed, became incurably lame, was not tried, and was got rid of.

No. 6. Bay mare, a trooper, making a noise. Operated on both ventricles by the trephine method. By this method both thyro-arytenoid muscles were exposed and were not atrophied.

Result. After two months not improved, and grunts now in addition to roaring.

Nos. 7, 8, 9. Special reports about these giving the history of the horses before and after the operation, for which I am indebted to Mr. McKenny. Nos. 7, 8 are the cases operated upon at the last Veterinary Medical Association of Ireland held on Nov. 29th, 1910.

No. 7. Bay gelding, four years old, 16-3 hands, flat ribbed, long delicate neck, very thin, unthrifty appearance, visible mucous membrane pale yellow, pulse soft and large, respiratory sounds, upper portion of lungs loud, lower portion crepitating.

History. Got by a "whistler," a large number of whose stock became "whistlers"; out of a sound-winded mare, dam of three other sound-winded horses, but were sired by other horses believed to be sound in wind.

The horse was trained at three years old, and was then sound, afterwards suffered badly from strangles, and ever since was a bad "whistler," and soon became distressed when galloped.

The horse was put out to grass after the operation, and has not yet been removed, but the owner reports that when the horse gallops, he can hear him making a hissing noise, but it is not the sharp distinct whistling noise that it made previous to operation.

No. 8. A bay gelding, six years old, 15-3 hands, good neck and well ribbed. A bad grunter, and made a very distinct whistling noise when galloped, but did not easily become distressed. Bought by a dealer without any history; auscultation revealed no abnormal sounds. Operation most successful, the whistling noise being

completely removed, and the horse remained a good stayer.

No. 9. A black stallion, 11 years old, got by a sire whose stock are well known to be very good and sound in every way. Up to ten years old this horse remained sound; he then suffered from a severe attack of influenza accompanied with a large submaxillary abscess. When he had sufficiently recovered to be exercised, it was noticed that on becoming excited, he made a snoring noise. He was given Iodide of potass. with the view of causing absorption of any thickening of the mucous membrane and abnormal exudation remaining about the throat. At the expiration of three weeks of this treatment he was much better, the Iodide of potass. was discontinued and Liquor arsenicalis was given in half ounce doses three times a day, mixed with two wineglassfuls of cod liver oil, and given with scalded oats; he then was put to his ordinary work, he made no noise when going slowly, but when going fast made a peculiar hissing noise in both the inspiration and expiration. At the end of another fortnight dram doses of powdered Nuxvomica and Sulphate of iron were given in place of the Liquor arsenicalis; this was continued for another fortnight, and alternately these were given as before stated. For three months his work was continued; medicinal treatment was discontinued for two months, at the expiration of which similar medicinal treatment as before stated, was repeated for another three months, during which time the horse occasionally suffered from slight colds, that is, coughed a little, and had a slight watery discharge from the nose. On each of these occasions the noise was more easily produced than usual, and assumed a character more like whistling, that is, it became shriller, and more marked in the inspiration than in the expiration, but it always remained more like a horse suffering from a cold than a pure "whistler," which I hold is quite a different sound. The noise made by a true "whistler" is, as the name indicates, a whistle, and is only heard in the inspiration, and the sound in the expiration is soft.

At the end of about eight months this horse was in strong work, and the day after an extra hard day it required to extend him for a long distance before the noise could be heard: it did not stop him. He then suffered from a severe cold and was laid up for three weeks; he was again gradually got into good working condition, but the noise was as bad as after he had suffered from the submaxillary abscess, and it was determined to remove the membranes from the laryngeal ventricles. Previous to the operation the lungs were examined and found to be sound.

When the horse was cast for the operation and during the administration of the chloroform, the jugular veins became enormously distended and pulsated; he was chloroformed cautiously and it took a long time to get him under its influence, eight ounces of chloroform had to be administered.

When the larynx was first opened we (three veterinarians) agreed that both arytenoid cartilages were acting; however, after a short time one said he thought the left cartilage was not acting as well as the other, and another stated that he thought there was a slight difference, and the third said he was of the opinion both were the same. The skin wound was made not quite so long as usual. The horse got up before he had completely recovered from the chloroform, staggered and fell heavily, and the breathing became very distressed; however, he was held down for fully twenty minutes, and when he got up he at once ate a mash of bran, and seemed no worse for his tumble, but his breathing was very loud and distressed; for the next five days he partook of no food and his breathing became so much worse that it seemed almost imperative to perform tracheotomy. On the sixth day his lungs became affected, he received some fever drenches, and his sides were stimulated with

mustard. Three hours afterwards he ate a small mash of bran, and slowly made a good recovery. However, up to the present, five months since the operation, the noise is no better than it was before the operation.

No. 10. Aged bay hunter gelding, a splendid hunter a loud roarer. Stays an ordinary hunt well, as on account of his big stride he is seldom fully extended, but when the hunt is very fast he shows distress. Both ventricles operated upon. The left arytenoid completely paralysed. Not yet tried.

Remarks. In no case did a horse die as the result of the operation. Some of the cases showed accelerated breathing for a few days after the operation, but No. 9 was the only horse which showed evident distress and decided dyspnoea lasting for five days after the operation. No. 10 was not affected in the least in his respirations at any time after being operated upon. The conclusion I have come to from the foregoing cases is that when the arytenoid is undoubtedly paralysed the operation is likely to be successful, but if the cartilage is not paralysed a successful result need not be expected. It is evident that many horses make a noise from other causes than paralysis of the arytenoid cartilage, and the noise is called roaring or whistling for the want of a better name. Up to the present I am sure many such cases have been operated upon as roarers or whistlers, and have been numbered as examples of failures of the operation. I feel convinced that the reputation of the operation is being damaged in this way.

No. 6 is a striking example of a horse making a noise without paralysis of the arytenoids, for both the thyro-arytenoid muscles were dark red and fleshy in this case, showing that they were not atrophied from paralysis. The loud grunting noise made by this horse when tried about three months after the operation was so extraordinary, resembling somewhat the roar of a lion, that it was thought there was some abnormal thickening in the larynx at the seat of operation. Consequently the larynx was opened in the hope that something might be done to remedy the defect—if present. When the interior of the larynx was examined the ventricles were found beautifully obliterated, the arytenoids standing well out of the lumen, and the mucous membrane throughout was as smooth as if nothing had been done to the larynx. There was no thickening of the thyroid cartilage either inside or outside the larynx. The roaring in this case was evidently not of laryngeal origin, as there was nothing in the larynx to account for such a noise.

DISCUSSION.

Mr. L. M. MAGEE said he had operated on a great many roarers and whistlers. In some cases he had stripped only one ventricle and in others both. He had had successes with both methods. One of the first horses he operated on was about the worst roarer he had heard. He only stripped about half as much of the left ventricle as he now takes away, and the horse came perfectly sound. It was difficult to know whether there was any advantage in stripping both ventricles when apparently only one vocal cord was affected.

He had had a great many successes with the operation, but of course he had failures too, but not many. If the horse was not sound afterwards he was generally greatly improved. Most of his failures were when he first commenced to do the operation and did not always strip the ventricle properly. He could not recall a case where the vocal cord was paralysed, and that when he removed the mucous membrane satisfactorily that the horse did not become sound or greatly improved. It was a difficult operation and one that required great experience and practice to perform properly. He was

firmly convinced that the operation was a good one and had come to stay. In operating through the thyro-cricoid ligament without cutting any of the cartilages, Prof. Hobday had revolutionised the operation.

He would like to make a remark on the attitude that many of the profession had taken with regard to the operation. It was very unfair for a man who had never done the operation, or perhaps never seen it performed, to condemn it and say there was nothing in it. If a man couldn't do it, or hadn't the pluck to try it he should not adopt such a dog-in-the-manger attitude. By proceeding on such lines very little advance could be made in their profession. (Hear, hear.)

The Hon. Sec. pointed out that at the next meeting Mr. Craig would give them a paper on "Roaring and Whistling," and he desired the assistance of members to obtain the trachea and larynx of horses that had been said to make a noise during life. Mr. Watson said he was perfectly certain no paper could be suggested that would be productive of such spirited discussion as a paper on roaring and whistling, and he urged members to assist Mr. Craig to obtain the materials.

A vote of thanks to the President concluded the meeting.

Experiments on Living Animals.

The total number of experiments performed on living animals in England and Scotland during 1910 by persons licensed for that purpose was 95,731. A report issued by the Home Office [219] shows that this exceeds by 9,454 the number of experiments performed in 1909.

From a classification of the experiments it appears that the vast majority of them—namely, 90,792—were not of a serious character, and did not require the administration of anaesthetics, being attended by no considerable, if appreciable pain. The remainder, 4,939 in number, included 2,942 experiments carried out under the provision of the Act that the animal must be kept under an anaesthetic during the whole of the experiment, and must, if the pain is likely to continue after the effect of the anaesthetic has ceased, or if any serious injury has been inflicted on the animal, be killed before it recovers from the influence of the anaesthetic. In 1907 experiments the initial operations were performed under anaesthetics, from the influence of which the animals were allowed to recover. The operations are required to be performed antiseptically, so that the healing of the wounds may, as far as possible, take place without pain. With regard to the 90,792 experiments performed without anaesthetics they were mostly inoculations, but a few were feeding experiments, or the administration of various substances by the mouth or by inhalation, or the abstraction of blood by puncture or simple venesection. The number of experiments performed in the course of cancer investigations was 49,662.

The number of persons licensed to make the experiments was 542, but 147 of the licensees performed no experiments. Tables are published which, the report observes, afford evidence that the licences and certificates have been granted only on the recommendation of persons of high scientific standing, and also that the licensees are persons who, by training and education, are fitted to undertake experimental work and to profit by it.

A separate part of the report relates to Ireland, where there were 254 experiments, performed by 16 licensees. *The Times.*

* As Diseased or Exposed to Infection

Royal Commission on Mines.

THE HORSES AND PONIES.

At the 85th sitting of the Commission, on December 13th, 1910, evidence was given by Mr. THOMAS EMERSON FORSTER, managing-director of the Cowpen Coal Company, Limited, working collieries in the neighbourhood of Blyth, Northumberland, producing upwards of 1,000,000 tons per annum, and employing about 400 horses and ponies. Describing the system of keeping the horses, he said: The whole stud is under the charge of a properly qualified veterinary surgeon, who makes an examination of the underground stables and ponies at each pit once a month, and a special examination of each pony a fortnight later. He is responsible for the general welfare of the stud, and stops any pony from working if it is, in his opinion, unfit to do so, reports any irregularity, defects in stabling or food, suspected cases of cruelty, etc., to the resident manager. He also makes a special report once a fortnight to me, as managing-director, in which all cases of illness or accident are set out, as well as the result of his examination of the ponies. He attends at the colliery office with this report, the resident manager and underground managers being present at the same time, so that any points arising out of the report can be at once inquired into thoroughly. His report also contains detailed particulars of the amount of food-stuffs consumed at each colliery, showing the quantity used per animal. The purchases of food are specially made by me, and every care is taken to secure the best obtainable. At each colliery a head horsekeeper is responsible for the horsekeepers doing their duty, and seeing that the veterinary surgeon's

instructions are properly carried out. He reports to the manager of his particular pit all cases of injury or cruelty or unfit ponies. It is his duty to see that the proper quantity of food is sent down for the stud under his charge, and that it is properly divided out by the horsekeepers. Each horsekeeper has, on an average, about 20 ponies under his charge, the actual number varying according to the position of the stables. These men go down in time to see that the ponies are fed and harnessed before going to work, and, after clearing up the stables, return to the surface until they go down again to receive water, and to feed and clean the ponies on their return from work. They have to report any injury and stop any pony from going to work if they think it unfit, until the head horsekeeper or veterinary surgeon has examined it.

The shoeing is done by competent shoeing smiths, who attend the different stables every day and replace or refit shoes. The saddlery is kept up by a saddlery contractor at a fixed price per pony. It is therefore to his advantage to see that good material is used, and the leather part kept properly oiled, and, as rubbing against the roof wears the harness, he is not long in complaining to the manager should any occur. All collars are fitted to each pony.

The ponies get two meals a day, and food is kept at the flats and landings for them during their shift. The average pony of about 12 hands gets about 14lb. of food per day, consisting of chopped hay, maize, beans, and oats, mixed in proper proportions. The putting and driving ponies work 8 to 10 hours, and are never more than 11 hours a day out of the stables unless under very exceptional circumstances, and in that case, never twice running. A stock of spare ponies is kept at bank so

that any additional ponies can be supplied at once. All new ponies are kept at least a fortnight before being sent underground, in case of infection. Before starting work they have a preliminary training at bank, and for the first week or so underground they are under the special care of reliable men or older boys.

The system I have outlined is, generally speaking, the same as that in use at other collieries in the neighbourhood, and has been practised at the Cowpen Collieries for upwards of 40 years. I have heard the allegations of cruelty to pit ponies. You might get isolated cases where a driver, a boy probably, loses his temper. In our experience at Cowpen over the last six years we have only had five or six cases, and none of them what you might call of a serious nature. I think everybody is quite agreed that to overwork ponies is a bad policy. If they get out of condition, and get overworked, you cannot get the coal out, and if you do not get the coal out down goes your output and away goes your profit. I think it is recognised that to keep ponies in good condition, and to treat them well, is essentially necessary for good mining. The case which has been put forward in respect to the ill-treatment of ponies has been exaggerated so far as our district goes, decidedly. It does not apply at all to our district. Our practice is never to work any ponies double shifts. There are ponies, where they work eight-hour shifts, which require occasionally a double shift because it is found on a short shift they really get too fresh; but where a pony is worked double shift it is not systematic, it is only occasionally. As a rule our principle is never to work any ponies double shifts systematically at all. All the men have instructions if they want more ponies to ask for them, and they get them.

Mr. HENRY EUSTACE MITTON, mining agent for the Butterley Company, Limited, who are raising coal from 15 collieries situated in Nottinghamshire and Derbyshire with an annual output of over 1½ million tons, was the next witness. He was assistant general manager for the Tredegar Iron and Coal Company, Limited, Monmouthshire, from 1900 to 1905, and previous to that held positions as deputy and underground manager at collieries in Derbyshire connected with the Sheepbridge Coal and Iron Company, Limited. In the course of his evidence he said: I have reports from the veterinary surgeon who is in charge of the horses for the Company. We have 61 horses on the surface and 501 underground. He makes a regular examination of all the horses once a month, that is, he and his staff. Of course one veterinary surgeon cannot possibly do it all himself. They go through the stables and examine the horses, not taking each horse, but taking them out here and there generally and specially noting any horses to which their attention has been called by the ostler or the under-manager. I have discussed this matter with the veterinary surgeon, and he considers that if it is optional so that he could go and select any one anywhere, and he goes and picks out horses here and there, he can see generally the whole of the condition of the horses, and if any horse is suffering and his attention is called to it, see the under-manager of the mine who is responsible for the horses, or the under-manager could ask him specially to see those horses who were suffering during the month. The horsekeeper keeps an account of all the sick or injured horses during the month which the veterinary surgeon sees.

The maximum number of days worked by one colliery is 259½ per annum, and the minimum 167½ days. The average number of days worked by all the collieries is 214 per annum. The highest average hauled per day underground by one horse during the year ending March 31st, 1910, was 21½ tons; the lowest average was 6½; the average hauled per day underground by all the

horses was 13½ tons. The highest average number of miles per day travelled under load by one horse underground during the year was 13; the lowest average was 6; the average number of miles per day under load travelled by all underground horses during the year was 7·8.

As to the average quantity of food consumed per day, over all the collieries the corn worked out at 8½ lbs. per horse, and the hay at 13·9 lbs. The total number of horses killed by accident was 10 out of 501, which is the total number underground. That is 1·9 per cent. An instance of an accident is the case of where a horse is coming down with some tubs and the locker breaks, or the horse puts his foot on the rail and slips, and the weight of the tubs throws him forward and breaks his leg or cripples him in some manner. He is destroyed in the workings; right where the accident takes place. So that by "killed by accident" I mean killed or seriously disabled and having to be destroyed. Nearly 8 per cent. of horses die every year; that is including those sent out which are old and worn out. The average height underground of our horses is 13 hands 2 inches. We have 19 partly-blind horses, and 6 totally blind, out of the 500. The horses are purchased by myself, subject to being passed by an experienced man as to age and soundness. I have a man who is kept on purpose; he is a farm bailiff who is experienced in horses, and he is responsible to see that the horse is all right. I generally prefer the age of five. They are tested by the "mallein" test for glanders by the veterinary surgeon. Then they have a fortnight's trial after being sent to the pit. After test, if satisfactory, they are allotted to the various pits where required, and name, age, colour, height, etc., are entered in the register under a special number, so that a full record is kept of the horse. It is the custom after the horse has gone down to allow it 48 hours in the stable underground to get its eyesight and settle itself. We do not allow any horse to stay if he exhibits any signs of temper when he is first put in the pit, such as kicking or jibbing, or baulking. We send him out and have him replaced, but the percentage of horses that prove unfit for the work and have to be returned does not amount to more than 2 per cent.

All the underground stables are cleaned daily and the horses are kept in single stalls. In most cases those stalls are divided by brick walls with the ventilation passing over the top. The brick wall is not brought right up to the top of the roof; there is sufficient space allowed for the air to travel over the top. In some cases we have posts and timber instead of the brick wall. The horses are daily bedded with clean sawdust, and out of 15 stables underground we have five stables lit with electric light. In all the stables the horses have drinking troughs supplied with water either from the surface or upper measures, and these troughs are filled ready for the horses when they come in from work, and are left filled when the ostlers go out of the pit. We limewash the stables out from time to time, whenever the manager of the mine considers it necessary. The stables and ponies underground are examined every month by a veterinary surgeon, who is retained but not fully employed by the Company, and the veterinary surgeon sends direct to me a report at the beginning of every month, on every underground stable, drawing my attention to any horses or ponies who are suffering from accident or illness, and any other matters which he thinks should be rectified or improved. I write the manager of the colliery, and send him a copy of the veterinary surgeon's report if necessary.

I have read in the Press and elsewhere general complaints of the treatment of ponies in mines. I think that they are unfounded, as is shown by the anonymous letter which was sent to the Inspector with regard to some horses under the Butterley Company. The charge which was brought against the Butterley Company was

absolutely groundless, and if the letters that have appeared in the Press are of the same character, I do not consider they are worth very much. I should say that the ponies underground are better than the horses on the top, as they are not subject to the variations in the weather. We have more horses on top with colds than we have underground. The oldest pony that I can trace is one which has been underground more or less for 24 years. I have seen this pony myself at our Waingroves Colliery quite recently. The pony looks aged, but he certainly seems to have plenty of life in him yet. The average working life of the ponies is from six to seven years. That is including horses killed by accident and dying, but not including the horses which we returned as wasters—horses which kick. Each horse is re-registered under a number and name, and then a blank and so many lines left below the number, so that if the horse is No. 700 and he is called "Tom," and "Tom" dies, the horse that replaces him is called "Tom," and he is numbered 700. We always keep the same number and name. We find that much easier to trace in our books.

The Midland Coal Owners, whom I represent in my evidence as well as the Butterley Company, have had enquiries made, and out of 30 collieries 17 connected with the Association in Derbyshire and Nottinghamshire replied that they maintain a veterinary surgeon who makes a report on all ponies underground. There would be no objection to that report being seen by the Inspector of Mines. The Inspector examines all the ponies. Some ponies going out are without food and water for eight hours at the Kirkby Colliery. This has been in vogue for six months, and I should say, from the examination of those ponies, it is not too long for them to be without water. I have a strong objection to watering ponies in the workings of a mine. In watering in a mine orders may be given for troughs to be filled and tanks sent out, and the manager believes that the ponies are being watered and fed in the workings, the result is if a pony has to be kept back it is assumed he has been watered, and that there is no hardship for him to stay back a few hours. What I have found from past experience in watering in mines is that very often these tanks do not get into the right district, and the result is that some ponies get too much water and others none at all. It does not do a pony harm to be without water for eight hours, and we have adopted at the Butterley Colliery a system that every pony and horse has to come back to his stable every eight hours to have a feed and water. I consider that is a better system than relying on the tanks being sent to the district.—*The Iron and Coal Trades Review.*

Cattle that died from Fright.

At Haslingden County Court, on Thursday, 3rd inst., before Judge Hane Hamilton, John Ward, of Park Farm, Church, sued A. Graham and Sons, contractors, Huddersfield, for £67. Mr. Broadbent, of Blackburn, was for plaintiff, and Mr. J. Harrop Dransfield, of Huddersfield, barrister, was for the plaintiff.

Mr. Broadbent said the claim principally arose from the death of five cows alleged to have been caused by the shock of blasting operations whilst defendants were carrying out sewerage works through plaintiff's farm land. In the latter part of 1909 the Church Urban District Council decided to proceed with a somewhat large sewerage scheme, and they entered into negotiations with the owners of certain estates through which the pipe track would pass. Capt. Petre was owner and plaintiff was tenant of a farm through which the pipe track ran. Permission to go through the land was given on condition that any surface damage should be made good.

Mr. Dransfield contended that under the act any damage arising from the exercise of these powers must be made good by the urban authority, and that it was impossible to sue any person the urban authority employed.

Mr. Broadbent said defendants were not servants, but independent contractors. The local authority on Nov. 23rd, 1909, entered into a contract for the construction of a main sewer from Fox Street to the outfall sewerage works at Coppy Clough. The contractors (defendants) commenced work about the beginning of 1910. For a distance of 180 yards the line of pipes had at one part to pass through plaintiff's land at a distance of 50 to 100 yards from his farm buildings, and at another part to within a few yards of the shippin and outbuildings. In the early part of the operations it was found that the land on plaintiff's farm was almost entirely of a rocky nature close up to the surface. This necessitated blasting operations, which were commenced in January and continued to the middle of May.

Mr. Dransfield said plaintiff had got all he could from the District Council, and all that he was doing now was trying to get from defendants what he could not get from the Council.

Mr. Broadbent said the Council paid £33 for disturbance of the pipe track itself, and denied their liability for other damage. The blasting was within a few yards of plaintiff's shippin. Witnesses would say that houses half a mile away were shaken by the explosions. Whilst the blasting was going on plaintiff bought on different occasions five newly-calved cows. Within a few days of the first of these being brought to the shippin it became nervous, ceased to give milk, and sickened. Its ailment was a mystery to Mr. Allen, the veterinary surgeon, and after a few days the cow died, though it had no signs of any organic disease. What happened with this cow happened with three others. In May Mr. Allen was attending the fifth cow. Whilst he was examining it he heard the reports of blasting, and after asking what it was he saw that the noise caused the cattle to jump with fright, and concluded that each of the cows had died from this shock. Mr. Allen would tell the court what a nervous animal a cow was, and particularly a newly-calved cow. This last cow whilst ill, but not suffering from any organic disease, was sold to a butcher, who would say that the cow was absolutely sound. Some fifteen years ago the butchers and cattle dealers of Blackburn successfully objected against the "one o'clock gun" at Blackburn being fired on Wednesdays because of its effect on cows. Plaintiff claimed £10 for each of the five cows, but they were worth £15 each. In addition £17 was claimed for damages by the contractors erecting huts on the land, and by their workmen breaking down fences and hedges and trespassing. This again was an absurdly reasonable sum to claim.

Mr. B. S. Daniels, steward for Capt. Petre's estate, said there was blasting two or three times a week. Cross-examined, he said he never made any complaint as to the way the work was done.

After plaintiff had been called,

Mr. H. B. Allen, veterinary surgeon, described the explosion he heard as "terrific." He attributed the death of the cows to nervous exhaustion, caused by the shock of the explosions. A cow was the more frightened by a noise which to it was mysterious.

Cross-examined, he said he had not previously known a case of this kind. If Professor Owen Williams said it was an unheard of thing for a cow to die from shock, that would not affect his (witness's) opinion. A post-mortem examination would not have revealed anything in a nervous complaint. He would swear the cows did not die from blood poisoning.

Jacob Haworth, wholesale butcher, Church, who

bought the last of the cows, said it was perfectly sound.

Mr. Dransfield said the sewerage was done under the Public Health Act of 1875, and under that Act the Urban Council were responsible if any damage had been suffered. If it were otherwise the work of a contractor would be impossible. Defendants had done their work well.

Mr. Broadbent said notice of this plea should have been given if it were relied on.

His Honour said he would carry the case as far as he could, and if it became necessary the contractors and the Council must settle the matter between themselves.

Professor Owen Williams, of Liverpool University, veterinary surgeon to the King, said he had never heard of a cow dying from shock. He should say these cows died from blood poisoning. It was very common for cows after calving to be afflicted with blood poisoning, and in many cases the symptoms were extremely vague.

William Wood, surveyor for Church District Council, said whatever damage the contractors did the Council expected the contractors to pay. The Council said the contractors were liable for these cows if they died through the blasting.

George Hy. Graham, one of the defendant firm, said the explosion was simply a dull thud, with very little vibration.

Mr. Dransfield asked that the District Council should be joined as defendants.

His Honour said the matter might be left with him. The Council would only want to do its duty. At present he said plaintiff had suffered damage to the extent of £40. Defendants and the Council should settle the matter between them from now and next Court, and he would then enter judgment on what they arranged.

The effect of this is that plaintiff is awarded £40 damages, the defendants and Church District Council being left to apportion this amount.—*The Observer and Times*.

The London Horse-Omnibus.

The London General Omnibus Company are selling off horses at the rate of 100 a week, and expect by the end of next month to have taken off the road their remaining 94 horse-omnibuses, and by a few weeks later to have sold their last horses. "We have got 1,300 horses left," said an official of the company, "and we are now selling 200 of them every fortnight. Before each batch is sold we take a certain number of omnibuses off the roads, and the last will come off about the last week in September. We are turning out 20 new motor-omnibuses a week from our factory. We do not, however, want to increase our fleet by this number per week at this time of the year and through the autumn and winter, so we are replacing 10 of the old omnibuses by new ones of the improved silent type each week." The striking growth of the numbers of motor-omnibuses and the decrease in horse-drawn ones in the last nine years is shown by the following table, showing the numbers of vehicles of each kind licensed on the streets on January 1st each year:—

	Horse	Motor		Horse	Motor
1902	3,736	10	1907	2,964	783
1903	3,667	29	1908	2,557	1,205
1904	3,623	13	1909	2,155	1,133
1905	3,551	31	1910	1,771	1,180
1906	3,484	241			

No figures are available for the present year, but the number of motor-omnibuses is now approaching 1,500.

The omnibuses will be broken up and the stables closed as the horses are sold.

Veterinary Inspection of Horses.

Circumstances are gradually forcing the question of veterinary inspection of horses at shows to the front. At the Clydesdale Horse Society Council meeting in the Inverness showyard last week, a communication was read from the Board of Agriculture asking whether the society would fall in with the suggestion of the Shire Horse Society and publish the list of stallions on the Government register in its studbook annually. An even more pressing phase of the same subject was raised by Professor McCall. Under the rules of the Victorian Government, all horses imported into Victoria from Scotland must be certified sound by the Highland Society or the Glasgow Agricultural Society. Neither of these societies has a veterinary inspection at its show. Although Principal McCall passed the horse over which the difficulty has arisen, his certificate has been refused, as it is not the certificate of a society, but of an individual veterinary officer. This raises the whole question of inspection in a rather acute form. It almost looks as if the Victorian authorities were trying to force the pace and impose public inspection at shows whether it is wanted in this country or not.

A Broken Pole-axe.—Hull Butcher and Employee fined.

At the Hull Police Court, on 19th ult., Ted Leathery butcher, was summoned for "not using, while slaughtering a blue roan heifer, such instruments, and not taking such precautions in the method of slaughtering, as might be requisite to secure the infliction of as little pain and suffering as practicable." George Ernest Coates, butcher, of Hull, who employed Leathery, was summoned for aiding and abetting his employee.

The evidence for the prosecution was that the beast was struck six times with the poleaxe before it was stunned. It was examined by a Corporation inspector, who found a piece of skin had been gouged out above the eye. The axe used by Leathery was found to be of little use, as half the punch was broken off and the shaft was insecure.

Mr. F. Payne, for the defence, intimated that the axe gave way at the first blow, and they had to go on and do the best they could with a broken axe.

The Magistrate remarked that if it were proved that there was only one axe in the slaughterhouse he would convict.

Mr. Payne: Does your Worship mean that there must be two axes in all slaughterhouses?

The Magistrate: Yes, I shall convict every time if there are not.

Mr. Payne said that he admitted there was only one axe. He said that the animal was bought by Mr. Ingram, and was to be slaughtered in the defendant's Coates' yard. Ingram struck the first blow, which brought the animal to its knees. Then the axe gave way. They could not in common humanity stop, and Leathery continued until the beast was killed. That, he contended, was the proper thing to do.—The Magistrate agreed.

Mr. Payne said that Coates was charged with aiding and abetting Leathery, whose action had been admitted to be one of common humanity.

The Magistrate remarked that he would convict. He considered that proper precautions had not been taken when only one axe, and that a defective one, was provided. Coates was fined £5 and £1 15s. costs, or two months, and Leathery £1, including costs, or 14 days.—*Meat Trades' Journal*.

London's Motor 'Buses.

The London General Omnibus Company were obliged to withdraw a third of the 'buses yesterday (Wednesday) afternoon, and if the dock strike continues and further supplies of fuel are not forthcoming, they will be forced to withdraw nearly as many more to-day. Even with the intended withdrawals the existing supply of petrol will not last more than three days. The company controls 2,000 vehicles, and there is a very serious likelihood of the men being thrown out of employment.—*The Daily Telegraph*.

Feeding of Horses in Russia.

Some interesting details relating to the diet and food of horses in Russia are given by the United States Consul in Moscow. Oats, he says, constitute three-fourths of the food upon which the Russian horse must exist during the twelve months of the year. Among the upper classes 12lb. or 14lb. of hay are fed daily to the carriage and racehorses, in addition to the 20 quarts of oats that are thought necessary for a horse during the 24 hours. This hay consists principally of timothy in Finland and the central and southern portions of Russia. As the result of a light hay diet, Russian horses are remarkably free from the heaves, though a more serious trouble originates from a continuous diet of oats, namely, cracked skins and heels, with open sores. City horses never taste a spear of green grass, but appear to keep in fairly good condition with practically no attention from the grooms. They occasionally are given carrots, but this does not apply to the average work horse, driven at all times of day and night, and subjected to Russian winters. His endurance is one of the marvels of the country. The feeding of corn, mixed foods, or prepared diets is unknown in Russia except among the racing fraternity, who have adopted American ideas from the trainers brought over years ago from the United States.

The Exportation of Horses.

During last year 9,915 horses were examined at City wharves before being exported abroad. Of these 211 were rejected. In the course of the year an Act was passed requiring the Board of Agriculture to appoint veterinary inspectors who should examine every horse proposed to be exported to the Netherlands and Belgium, and grant a "permit" for those found suitable for shipment. Power was given to charge for so doing 2/6 per horse. The City Corporation approached the Board with a view to the allocation of a proportion of the fees so received in relief of the expenses incurred by them as the local authority in enforcing the Act, but were informed that it was not within the power of the Board to comply with the suggestion.—*The Times*.

Leaving Carcasses Unburied.

At Dumfries a farmer was recently charged with having permitted the carcasses of three sheep and twelve lambs to remain unburied in fields on his farm, to which dogs could gain access, contrary to Section 6 of the Dogs Act, 1906. On behalf of accused it was pleaded that he had simply been following the usual practice of the district at lambing time. In ordinary circumstances when a sheep died the practice was to skin it and bury the carcass, but that could not be done at lambing time, because if men were engaged skinning sheep and afterwards worked among lambing ewes, the ewes were liable to contract inflammation. The practice was to leave the dead sheep lying for a few days, when the wool could be pulled off and saved. In the case of lambs the custom

was to take off their skins and put these on other lambs, so that the mothers of the dead lambs might look after them as their own. The Sheriff said it was a very objectionable practice. It might be that meddling with dead sheep was a very bad thing for those attending to the lambing, but the answer to that was that someone else should be got to see to the dead sheep. In imposing a fine of £1, he hoped it would be taken as a warning against the general practice.

Plucking Live Geese.

Though scarcely within the scope of this department of the *Gazette* we are asked for an opinion on the subject matter of the plucking of live geese. It is to our minds just a work of necessity, and as such is justifiable be it cruel or otherwise. It has been proved that geese (domestic geese that is to say) grow coarse, become verminous, thin, scraggy, and unhealthy if left unplucked and, *ergo*, useless. Let the critics think the matter out calmly, and they must admit that such a process is every bit as necessary as the castrating of animals not intended for stud purposes, the dehorning of cattle, or any other operation severe or simple that often has to be done on some animal or other. It seems to us many folks dub anything "cruel" that happens to be "painful."—*The Farmers' Gazette* (Dublin).

The Dublin Horse Show.

The forty-fourth annual horse show of the Royal Dublin Society is announced to take place at Ballsbridge on Tuesday, the 22nd August, and three following days. Valuable money prizes, cups, etc., are offered for thoroughbred stallions, brood mares, and yearlings, hunters, riding cobs and ponies, and harness horses. Two special jumping competitions over the course are provided—one for British military officers quartered in Ireland, and the other for naval and military officers of any nationality.

Personal.

Mr. J. BIRKENSHAW IDLE, M.R.C.V.S., Ridding Mount, Harrogate, a graduate from the Royal (Dick) College, Edinburgh, has been selected by the B.S.A. Co., to fill an appointment in Africa. Mr. Idle sails from London for Salisbury, Rhodesia, on Sept. 2nd.

OBITUARY.

ERNEST ASHWORTH, M.R.C.V.S., Helmschore, Manchester
Graduated, New, Edin : May, 1900.

The interment took place at the family vault at Ramsbottom on Saturday, July 29th. The deceased was 32 years of age, and served in the South African War. He was brother to the late Mr. A. E. Ashworth, manager of James Barlow and Sons, of Sunnysbank and Albert Mills, Helmschore, and President of Helmschore Conservative Club. He leaves a widow and three children.

CHAS. K. DOBSON, M.R.C.V.S., Holbeach, Lincs.

• Lond : April, 1888.

Death occurred on July 22nd from sarcoma of neck. Aged 44 years.

WALTER HENRY CAMPSALL, M.R.C.V.S., Hartington, Derby.
Edin : Dec., 1896.

Mr. Campsall died on Aug. 4th, at his residence, from, cardiac failure, at the age of 42 years.

MASON.—On August 3rd, at Grafton House, Leeds, in her 45th year, Edith C., wife of A. W. Mason, F.R.C.V.S. Interment at Lawnswood Cemetery, on Saturday, Aug. 5.

CORRESPONDENCE.

PROFESSIONAL FEES.

Sir,

I think it only right to say that since the appearance of my letter in *The Veterinary Record*, I have had a communication from the firm of whose fees I complained, saying that I was in error about the charge of 4/6 being their fee for treating a cat for a week in their hospital, and that their fee was 5/- per week. In justice to myself, however, I should like to add that the lesser sum was given me twice, on the second occasion by one of the members of the firm in question.

In reply to "*Vis unita fortior*," perhaps my letter was not very explicit; so far from gaining a client, I lost one. A former client had evidently been scared by my fee of 10/6 a week, and had made enquiries of the firm in question as to their fees, and found that this was less than half mine. He then had a cat treated by them, and when summoned by me in the County Court for payment of my account entered the defence that my fees were exorbitant, that he could get the same hospital treatment for less than half my fee. Naturally I questioned this, when he produced the receipt authenticating his statement.

To the London veterinary surgeons who have written me suggesting a round table conference to discuss the fee question, I should like to say that for the next two months London veterinary surgeons will probably be pretty much scattered, but that if after Michaelmas, they are still in the same mind, I should be pleased to assist in making arrangements for such a meeting.—Yours, etc.,

H. J. R. POPE, M.R.C.V.S.

Sir,

It is possible that the public discussion of this subject in your columns may do some little good, provided that such discussion is conducted civilly and reasonably. I make this proviso because, though the first of the two letters you have published was quite unobjectionable in this respect, the tone of the second prompts the reflection that any such discussion might easily degenerate into a series of anonymous ebullitions of spite and stupidity directed against one successful firm. I, however, who am a "mere rural person," and do not keep an infirmary at all, only wish to call attention to one aspect of the question, which should not, I think, be disregarded. This question of fees for the keep and treatment of dogs and cats resembles many other subjects connected with veterinary work and remuneration in one respect—that, though it is partly a professional question, there is also a considerable element of trade in it. That being so, we ought fairly to consider the actual monetary cost to the veterinary surgeon of keeping a canine or feline patient.

The just and reasonable weekly terms for the keep and treatment of cats are mentioned by your two correspondents; and I venture to suggest that such questions as the following deserve consideration in connection with any estimate of these. What is the average cost of a cat's food per week, especially of a confined one taking no exercise? What is the cost of a cat's house-room?—and here it should be remembered that a cat's cage is generally an inexpensive and fairly durable article of furniture, and that a goodly number of such cages can be superposed in a room which, if unfurnished, would only command a very low rent indeed. What fraction of an infirmary attendant's weekly wage should be put down to the account of an individual cat?—one attendant can look after a good many. All these points, and other similar ones, should be, and no doubt are considered by the men who keep canine and feline infirmaries, but there seems to be a conspiracy of silence regarding their details. It would be a new thing if the results of a few calculations of this sort were made public; but I fancy the novelty might prove an instructive one.

There is certainly a great difference between a weekly charge of 4/6 per week, and a minimum one of 10/6. I

know that the latter is quite the usual one in the West End of London, and a very common one elsewhere—indeed, I think I could name provincial veterinary surgeons who habitually charge more. But is not the disparity capable of two interpretations? One, of course, is that 4/6 per week is "ridiculous." Another is that veterinary charges in general for keep and treatment of small animals in infirmaries are unreasonably and extortionately high. Perhaps some of your readers who themselves keep infirmaries will write and try to disabuse my mind of the latter impression.—Yours faithfully,

"RUSTICUS."

MR. KIRK'S APPEAL CASE.

Sir,

May I ask your courtesy to allow me to bring to the notice of your readers the fund which has been organised to provide the sinews of war in defending the veterinary surgeons' right to use the College crest.

As most members of the profession are aware, Mr. William Kirk, M.R.C.V.S., has successfully proved to the satisfaction of Mr. Curtis Bennett, the Bow Street magistrate, that the profession has this right. Against that decision the London County Council is appealing in the High Court, and to defend that action money will be required.

Since this is a matter affecting a large number of men in the profession, it has been felt to be unfair to let Mr. Kirk bear the whole cost. Those members who use the crest will, if the action is undefended, have to pay for its use annually. If they subscribe to an adequate defence fund, it is hoped our right will be established once for all.

An account has been opened at Parr's Bank, Camden Town Branch, and cheques should be made payable to the undersigned there. "To help promptly is to help twice."—Yours faithfully,

HAROLD A. WOODRUFF.

Royal Veterinary College, Camden Town.

August 9th.

FLIES.

Sir,

Does any veterinary surgeon know of a good dressing to ward off flies from horses and cattle. Country practitioner would be very grateful for any hints.—Yours, etc.,

A. B. C.

RE SWINE FEVER.

Sir,

I have received several congratulations upon what I have tried to fathom respecting this disease, and beg to tender my best thanks. The subject is open to criticism, so my suggestion on the eradication of this disease are:

- (1) That the Board of Agriculture should see that boars and sows are not kept too long for breeding.
- (2) That piggeries should be better constructed as regards drainage, air spaces, etc., and pigs not overcrowded.
- (3) That market pens should be made impervious barriers, and no contact allowed between each lots.
- (4) That unhealthy looking pigs should not be exposed for sale.
- (5) The Board of Agriculture should send delegates to other countries to see that the waste of pig food in England which, if mixed half weight for weight with meal, would produce bacon and pork enough for our population if properly collected. Holland can produce pork profitably, and send it to England below 6d. per lb. Why should not we do so?—Yours, etc.,

GEO. UPTON.

Prophylaxis and Treatment of Influenza and all Febrile Diseases of Horses.

INFLUENZA ANTITOXIN VETERINARY (P.D. & Co.), obtained from the blood of horses which have been immunised against influenza, is a remarkably efficient agent both for the prophylaxis and treatment of febrile diseases in horses, particularly influenza (pink eye, catarrhal fever or shipping fever) with its complications of cough, laryngitis, bronchitis, strangles, pneumonia and purpura hæmorrhagica.

Mr. G. J. Bissell, who maintains a racing stable in Kentucky, and who has had considerable experience in shipping horses, writes as follows :—

"It is now over two years since I started to use your Influenza Antoxin as a preventive. Since then I have never had a case of influenza. I have shipped young horses from Canada to Cuba and back. Formerly I carried \$16,000 to \$20,000 insurance on my stable of race horses; now I carry very little, although I have in training from twenty to thirty horses. If it had not been for your Influenza Antitoxin I would have certainly given up a racing stable of horses."

J. E. King, Assistant State Veterinarian, St. Louis,

after four years' experience with Influenza Antitoxin, states that it will abort strangles and cause the tumours to gather and discharge in from 24 to 36 hours, and in pneumonia it enables the veterinarian to save 90 per cent. of those grave cases which invariably die under medical treatment alone.

G. W. Dunth, Consulting Veterinarian of the Michigan State Live Stock Sanitary Commission, states :

"Its power to arrest the action of the influenza toxin seems almost phenomenal."

Supplied in Vials containing 30 C.C.

PRACTICES FOR DISPOSAL

SOUTH EAST COAST. Receipts 1910 £415. Good house, kennels, etc. Very well fitted surgery. Rent £40. Premium £450 and valuation.

SOUTH OF ENGLAND. In present hands 24 years. Receipts last two years average £835 including appointments £70. Convenient house, rent £21, larger house available if preferred. The practice has been worked principally by an assistant who would remain if desired. Premium only £800.

SOUTH COAST PARTNER WANTED. Receipts about £800 per ann. Good house available at moderate rent.

YORKS. Practice principally horse and cattle. Books 1910 show £575. Large convenient house with model stables for seven horses. Well fitted surgery. Rent £75. Practice very compact and easily worked. Premium £375.

NEAR LONDON. Present hands 9 years. Small house rent £30, the practice is principally canine and is easily worked. The returns are stated to be about £400 per ann. Premium one year's purchase.

KENT. High-class mixed practice, returning about £650 per ann. Good premises to be let on lease would be sold. Premium £600.

YORKS. Premium £250. Receipts 1910, £330. Rent £40. Stables and yard almost clear rent. Good agricultural and breeding district. Present hands nearly 20 years. Good house.

LONDON. Thoroughly sound practice, established over 100 years. Receipts about £1200 p.a. Fine house and thoroughly convenient premises. Rent £90. Practice is principally horse. Receipts increasing. Premium one year's purchase.

SOUTH COAST. Old-established Practice for Sale, returning about £550 per annum. Present hands five years. Convenient house, rent moderate. Premium £500.

LONDON. Present hands 30 years. Vendor retiring. Mixed practice. Rent £75. Receipts average £1073. Premium one year's purchase. Strongly recommended.

SEASIDE. Partner Wanted in old-established Practice capable of great increase. Receipts approximate £700. Working expenses low. Good house, rent £60. Premium for half-share £350.

SOUTH OF ENGLAND. Receipts average £650. In present hands 13 years. Usual fees. Good house, three stalled stable, four loose boxes, kennels, cat house, etc. Rent £85. Delightful residential locality. Vendor is well-known to us. Premium £750.

SCOTLAND. General mixed practice returning nearly £700 per annum. Contracts and appointments produce £250 per annum. Practically no night work. Established 30 years, 17 years in present hands. Good house, property of vendor. Rent £60. Premium one year's purchase.

OR M.R.C.V.S. wanted for 10 days to fortnight, to act as locum in country practice, from Aug. 23rd. State terms. Address, 3083 V.R., 20 Fulham Road, London, S.W.

Mallein and Tuberculin

MEMBERS of the Profession may obtain Mallein and Tuberculin on application to the Principal, Royal Veterinary College, Camden Town N.W., on the following terms: in bottles, 6d. per dose. Minimum quantity supplied, two doses. In hermetically sealed tubes, containing one dose each (specially suitable for use abroad) 1s. per dose.

G. H. PICKWELL, M.R.C.V.S.

Locum:

73 Victoria Mansions,
South Lambeth Road, S.W.

HUGH R. SINGLETON, M.R.C.V.S.

LOCUM TENENS.

Disengaged August 18th,
44 St. Michaels Road,
Bedford.

LOCUM TENENS

WALTER G. GREEN, M.R.C.V.S.,

c/o Chas. Haywood, Esq., M.R.C.V.S.,
Millstone Lane, Leicester.

Wanted

M.R.C.V.S. 1906, desires partnership, with view to early succession, in good-class general practice, hunting district preferred. Address 3086 V.R. 20 Fulham Road, London, S.W.

For Disposal

PRACTICE, town and country, old established, returns about £400. Within less than an hour from London. To be sold cheap. Address, 3087 V.R., 20 Fulham Road, London, S.W.

As Assistant

CLASS D student, up at Xmas, desires engagement up to end of September. Has been assistant in mixed practice. Address, 3088 V.R., 20 Fulham Road, London, S.W.

As Locum or Assistant

M.R.C.V.S., (1910) requires position as above, used to country practice, and practical. Address, 3089 V.R. 20 Fulham Road, London, S.W.

Wanted

ASSISTANTSHIP by M.R.C.V.S., thoroughly practical, reliable, post graduate, and abstainer. Address 3308 V.R., 20 Fulham Road, London, S.W.

Wanted

LOCUM for fortnight, from August 26th, for country practice. State terms. Address, 4308 V.R., 20 Fulham Road, London, S.W.

All communications respecting advertisements should be addressed to

H. & W. BROWN, 20 Fulham Road, London, S.W.

Tracheotomy Tubes

MISS JONES, successor to F. B. Jones, M.R.C.V.S., still continues to supply the Special Tracheotomy Tubes patented by her late father. Special terms to Veterinary Surgeons. Address, 86 Kimberley Road, Leicester.

As Locum or Assistant

FINAL year student (29) offers services as above, extensive experience as locum, mixed and dog. Ride and drive, disengaged after September 2nd. Address, S. Woods, York House, Old Leake, Nr. Boston.

Wanted

PRACTICE, returning from £600 to £800 a year with prospect of increasing, lowest cash price and all particulars, in confidence to 6308 V.R., 20 Fulham Road, S.W.

Practical Assistant

WANTED for South London practice. State full particulars. Address, 5308 V.R., 20 Fulham Road, London, S.W.

To Veterinary Surgeons

M.R.C.V.S., (1899) wants post as assistant, steady. References furnished on application. Address, 2081 V.R., 20 Fulham Road, London, S.W.

Locum Tenens

M.R.C.V.S., thoroughly used to country practice and holding testimonials as to ability and general character from many practitioners, is always open to engagement when not actually filling a post. Permanent Address, "Locum," 59 Gascony Avenue, London, N.W.

Wanted

ASSISTANT for mixed practice. Must be able to drive. Apply, giving references and stating salary required. Address, 2082 V.R., 20 Fulham Road, London, S.W.

Pupil Wanted

VACANCY occurs in an extensive mixed country practice in the Eastern Counties for a gentlemanly youth as pupil. Premium required. Address, 2084 V.R., 20 Fulham Road, London, S.W.

Assistant

ASSISTANT wanted in busy London practice (horse and dog), recent graduate preferred. Address, 2085 V.R., 20 Fulham Road, London, S.W.

For Sale

SMALL practice, no qualified opposition, increasing every year: owner giving up owing to ill-health. Returns about £200: No horse required: genuine. £85 including drugs and instruments. Motor cycle can be had. Address, 2088 V.R., 20 Fulham Rd., London, S.W.

Partner Wanted

IN extensive, old established horse and dog practice on the South Coast. Good contracts, average returns £650 per annum, with room for considerable increase. Address, 1081 V.R., 20 Fulham Road, London, S.W.

To Veterinary Surgeons

CLASS D student desires situation; has seen practice. Services for board and expenses. Address, "Vet. Student," 11 Warrington Place, Dublin.

As Locum Tenens

M.R.C.V.S., recently qualified, is open for engagements as above from October 1st. Excellent reference of four years pupillage in country practice. Total abstainer. Ride, drive and cycle. Address, "Vet." 4 Marlborough Road, Waterloo, near Liverpool.

Practice Wanted

WANTED, within 100 miles of Manchester or Liverpool, genuine established practice or good nucleus. Immediate settlement. Confidence observed. Address, 1108 V.R., 20 Fulham Road, London, S.W.

For Immediate Disposal

M.R.C.V.S., about to take appointment wishes to sell country practice, in good district, Scotland. C.C. appointment. Doing fully £300. Small price for quick sale. Address, 1087 V.R., 20 Fulham Rd, London, S.W.

To Veterinary Surgeons

LOCUM, assistant, branch manager, veterinary surgeon desires permanency, sporting, hunting, country practice. Experienced, reliable, practical, hard worker, castrate standing, good obstetrician, 34, single. Excellent references, interview. Address, 5074 V.R. 20 Fulham Road, London, S.W.

For Disposal

DEATH vacancy, Staffordshire, horse and canine practice, situated in centre of town, receipts £250 per ann., could be greatly increased. Good house, and kennels; working expenses small. Good introduction. Reasonable to immediate purchaser. Address, 3075 V.R. 20 Fulham Road, London, S.W.

For Immediate Disposal

YORKS, North Riding. Wanted, reasonable offer. Receipts over £300, good house to go with practice. Rent £12. Good agricultural and breeding district. Present owner 27 years; no opposition; C.C. appointment; introduction given. Address, 5307 V.R., 20 Fulham Road, London, S.W.

Chlorodyne

FOR SALE, a large quantity of Chlorodyne, full strength, B. P. 1885, at 2/- per pound. H. J. Pratt, Wholesale Druggist, Cleckheaton.

Binding

THE PUBLISHERS bind the Annual Volume in Cloth, lettered for 3/6, or Half Roan, cloth sides, 4/6, (uniform with Vols. I. to XXII.) These prices include carriage (parcel post) one way, to country subscribers. Position of Plates is noted in Index.

Notice

WILL gentlemen wishing to advertise in this column please note that our time for receiving is Thursday MORNING, and that 2 p.m. is "Latest."

CHEAP BOTTLES.

3oz. and 4oz. 6/- per gross, 6oz. and 8oz. 7/-, 10oz and 12oz. 9/-, 1oz. W. F. Vials 4/- 1½oz. do. 4/6, 2oz. do. 5/- per gross. Cash with order. All sizes in Poison and other bottles and jars quoted for, also a quantity of 4, 6, and 8oz. named medicals 5/6, 12, and 16oz. 7/- per gross. Carriage paid on orders within 70 miles.

Beaconsfield Road, Acton Lane,
Chiswick, London, W.

**Non-Poisonous,
Non-Corrosive,
Soluble in Cold Water.**

CHINOSOL

**Active Antiseptic,
Strong Deodorant,
Powerful Germicide.**

Practical experience for years past proves that Chinisol in solution or ointment readily penetrates diseased tissue, thoroughly cleanses and keeps healthy all kinds of wounds, favours granulation and speedy healing, mostly without a scar, and promotes the growth of hair. Chinisol is supplied in

POWDER.

CHINOSOL PURE POWDER for therapeutical preparations used *INTERNALLY*.

CHINOSOL VETERINARY POWDER for lotions, ointments, etc., for *EXTERNAL* use.

CHINOSOL CRUDE GRANULAR FORM } for prompt production of disinfecting fluids for odourless disinfection.

CHINOSOL CRUDE POWDER F }

CHINOSOL SPRINKLING POWDERS for disinfecting and deodorizing stables, sheds, styes, kennels, fowl-houses, etc.

Also **ANTISEPTIC DRESSINGS, OINTMENTS, SOAPS, PESSARIES, CHINOSOL BORACIC DUSTING POWDER, VETERINARY EQUIPMENT, etc.**

Write for full Price List, also for **POCKET CIRCULAR** for *VETERINARY PRACTICE* giving full particulars of treatment of **MILK FEVER, ABORTION, INFECTIOUS VAGINAL CATARRH** in *COWS*, and a great number of approved formulae.

NOTE.—Buyers of our preparations should in their own interest insist in receiving **ORIGINAL PACKAGES** bearing our trade mark with name and address of the Company and full directions inside, they should reject all packages not answering above description **AS NOT GENUINE** and inform us when such are offered.

Sold by Messrs. **Hewlett & Son, Ltd., London;**
Wyleys, Ltd., Coventry.

And all **WHOLESALE CHEMISTS** deal

TABLETS.

COMPRESSED TABLETS (disc shape) containing **FIVE EIGHT or FIFTEEN GRAINS** Pure Chinisol for internal administration in dry form or solution.

VETERINARY TABLETS (square shape) containing 46 grains Veterinary powder for external use only, to promptly prepare lotions, ointments, etc., of given strengths.

SANITARY TABLETS (square shape) containing 45 grains Crude Chinisol for the immediate production of disinfecting fluids of given strengths.

Saloform Pessaries.

The New Uterine Antiseptic

Highly recommended by many eminent
Veterinary Surgeons.

PRICES: Ordinary Strength, White.

4/6 per doz. 48/- per gross.

Extra Strong, Yellow.

6/6 per doz. 72/- per gross.

Sole Proprietors—

HARKNESS, BEAUMONT & CO.,

Wholesale Chemists,

EDINBURGH.

Veterinary Surgeons have for long keenly felt the want of something which could be used with good results as a Uterine Antiseptic and which at the same time could be quickly and easily administered. After many trials, and with the kind co-operation of some able Veterinary Surgeons of great experience in parturition cases, we have succeeded in producing

a Pessary made with a non-oily base which does its work efficiently and at the same time is non-irritant—in fact, soothing in its effect. They are of great use in parturition in cows or mares; and if administered immediately after parturition they will keep the Uterus clean and healthy, and prevent the after-birth becoming foul.

Veterinary Surgeons in various parts have highly recommended them, and there is an increasing demand for both kinds.

Customers are requested when ordering to state which kind they prefer.

A RECENT UNSOLICITED TESTIMONIAL.

AINSWORTH WILSON, ESQ., F.R.C.V.S.,
writes:—

"I have used the Saloform Pessaries supplied by Messrs. Harkness, Beaumont & Co., of Edinburgh, with good results in various diseases of the genital organs, both in mares and cows, more especially after parturition. They are particularly useful in retention of the afterbirth, with septic complications. It is often impossible to attend more than once a day to irrigate the uterus; in such cases it is good practice to leave one or two of the "extra strong" pessaries *in situ*. I have found them an excellent substitute for Iodoform and other well known non-irritating antiseptics. I feel justified in recommending them to the profession.

Witham, Essex.

THE VETERINARY RECORD

A Weekly Journal for the Profession.

EDITED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1206.

AUGUST 19, 1911.

VOL. XXIV.

THE KENNEL CLUB AND THE VETERINARY PROFESSION.

A certain amount of doubt is always attached to an uncorroborated assertion appearing in a single newspaper, especially if its details are vaguely stated. We cannot, therefore, accept the account which we print elsewhere of the Kennel Club Committee's action towards two veterinary surgeons without some reservations: but it certainly looks, upon the face of it, as if the veterinary profession had received a great and unjustifiable slight. So far as we can gather the facts, it seems that two veterinary surgeons at a recent large London dog show rejected two dogs belonging to one kennel on account of skin disease, that the exhibitor complained to the Kennel Club with respect to one dog only, and that the Kennel Club Committee—apparently not choosing to recognise the obvious bearing of the second dog upon the case—upheld the complaint. We do not know the Committee's reasons, but we may suspect that the personal influence of the exhibitor or his friends was not without weight.

Our contemporary suggests that large dog shows will become a "hotbed of canine disease" unless the Kennel Club Committee support the decisions of veterinary surgeons. Large dog shows, crowded as they are with dogs and dog fanciers from infected kennels, are really hotbeds of infection already; but they would certainly become much worse were visibly affected or suspicious dogs allowed to be benched. Veterinary surgeons alone have prevented that in the past, and their task has been neither an easy nor a pleasant one. It is responsible and difficult at the best; it may mean offending a client; and it is often rendered more harassing by the voluble abuse of disappointed exhibitors, perhaps delivered before a large audience.

If, in addition to all these disadvantages, a veterinary surgeon has to work under the constant fear of having his decisions over-ruled by the Kennel Club, the result will probably be that many practitioners will refuse to act at shows at all, and that those who do act will be afraid to inspect rigidly. For this reason the Kennel Club should uphold the decisions of veterinary surgeons unless the clearest proof is adduced that a rejection has been inexcusable. No evidence of any such proof appears in the case before us; all the evidence, on the contrary, suggests that the rejection was more than justifiable.

THE "NATIONAL" EXCURSION.

We omitted to acknowledge last week the source of the two photographs of the "National" excursionists which we reproduced. The small group of teachers and examiners at Llanberis was taken by Prof. J. D. Stewart, of Sydney University, N.S.W. The larger group at Beddegelert was taken by Mr. R. S. Rowlands, of Abergelle, President of the North Wales V.M.A. To both these gentlemen we offer our hearty, if somewhat belated, thanks for their kindness.

MORTALITY AMONG PIGS.

During the last nine months one hundred dead pigs have been reported to the City veterinary officials. A post-mortem examination is made in each instance, and it is of some interest to note the ailments and diseases which account for this mortality.

It is the exception to find that the pig owner has called in veterinary aid, and the remedies and various concoctions used in the treatment of porcine ailments would make the subject for an interesting and amusing article. For example, the following drugs appear to be favourites in this district: comfrey, Spanish juice, antimony, black sulphur, syrup of poppies, Beecham's pills, chamomile tea, and castor oil.

In the majority of cases the piggeries are badly constructed, damp, and not provided with adequate drainage. Many folks seem to abhor the use of whitewash, and the writer feels confident that if more lime were used about piggeries there would be less disease. It is also advisable that pig owners should thoroughly disinfect the premises before the introduction of fresh stock.

At this time of the year flies are very troublesome while opening carcasses, and the writer usually smears his arms and hands with an emulsion of sassafras oil and olive oil, which also has the advantage of preventing the nauseating smell of "dead pig" adhering to one's hands.

The pigs examined post-mortem were of all ages and sizes, but the majority could be classed as "wrecklings" or "Rutlands." The lesions found were as follows:

Tuberculosis	22	Strangulated hernia	2
Pneumonia	16	Anthrax	2
Enteritis	7	Pleurisy	2
Swine erysipelas	6	Gastritis	2
Swine fever	5	Endocarditis	1
Suffocation	5	Bacterial necrosis	1
Ascites	4	Metritis	1
Pulmonary congestion	3	Epilepsy	1
Cirrhosis of liver	3	Peritonitis	1
Verminous bronchitis	3	Hydrothorax	1
Internal hæmorrhage	3	Broken back	1
Pericarditis	3	Constipation	1
Rickets	3	Liver disease	1

Tuberculosis was generally found to be advanced. It is most seen where the pigs have been fed on the third stomachs of diseased cattle—care not having been taken in the selection of the food. One frequently has occasion to examine post-mortem every member of a litter, and when tuberculosis affects all, the sow's mammary gland should be carefully inspected.

Pneumonia is usually of the lobar type, and the writer is inclined to consider that feeding pigs on steaming food affects the constitution, and the mischief appears to be done when the animal returns to its damp bed.

Enteritis was in most cases associated with the presence in large numbers of *Ascaris suillæ*.

Anthrax. One of the cases examined by Mr. J. Spruell, D.V.S.M. (VICT.) possessed a spleen measuring 38½ inches in length. From external examination there was nothing in the two cases to make one suspect anthrax.

Broken back. In this case the 13th thoracic vertebra was found smashed.

Bacterial necrosis was found in the liver of a sucking pig. The organ was studded with degenerating centres from which films were made which aided diagnosis.

Liver disease. Under this heading I have placed one pig. Attached to the liver, stomach, spleen, and mesentery were very numerous yellow, pea-like sacs of pus. A medical pathologist who was interested in this case diagnosed the condition as portal pyæmia. Films were made and examined for the Ray fungus and Tubercle bacillus, but with negative results. It is probable that these small sacs were degenerated hydatid cysts.

W. J. YOUNG, F.R.C.V.S., D.V.S.M. (VICT.)
Sheffield.

VOLVULUS, TWIST OF THE SMALL INTESTINE.

The accompanying photo, taken by my friend Mr. Jos. Pattinson, chemist, of Aspatia, is an excellent representation of volvulus or twist of the ileum portion of the small intestine of a 15-year-old Clydesdale mare. The animal had been a very successful breeder and a good worker, and was never known to have a day's sickness all her life.

The case occurred on the 24th June last; the mare had been at work the day before and was turned out into the grazing pasture for the night along with the other horses, she was brought in about 6 a.m. and had her usual feed of oats which she cleared up; about an hour after she was noticed to be pained, lying down and getting up. Her owner, Mr. T. Bouch, of The Sun Inn, Aspatia, thinking she had an attack of colic, gave her a colic draught which he had by him, but this gave no relief, other quack nostrums were used but without any effect, and at 1 p.m. I was called in, and found the poor brute in a very bad form, black wet with perspiration, which was running down her face and neck and over her hoofs, I watched her for some little time and then made a careful examination. Exploring the rectum with the hand, I found the large bowel displaced as it were, and pressed back into the pelvic cavity, the mare strained very hard against me on introducing my hand into the bowel; she was suffering great pain, getting up and down, rolling about and on to her back, and in this latter attitude she seemed to feel a little relief.

I may here state that whenever I have a bowel case, and should the patient roll on to the back with the legs up and against the wall, no matter what may be the position, I leave it alone as long as it keeps quiet and easy, and do not allow anyone to interfere, as I have a fancy that if there be a twist, loop or invagination of the bowel it will at times right itself by the animal balancing itself on its back and thus lying maybe for twenty minutes or even up to two hours, after which the beast will roll on to its side, get up, give itself a shake, and commence to eat. I have had cases that have recovered suddenly in this manner after so comporting themselves, which leads me to press this view. There is, however, nothing to equal abdominal trouble for the post-mortem to reveal "the errors of diagnosis."

I do not favour the idea that twists in the bowels of the horse are caused by rolling about; not all the rolling and tumbling in the world, at least to my mind, could produce a twist like the one in the photo. My idea is that they are formed by excessive spasm of the longitudinal and circular coats of the walls of the intestine pulling against each other as it were, accompanied by increased peristaltic action of the bowel, and when I meet with an acute attack of colic in the horse, I have the patient put in a field if possible and allow it to have its full swing at rolling.

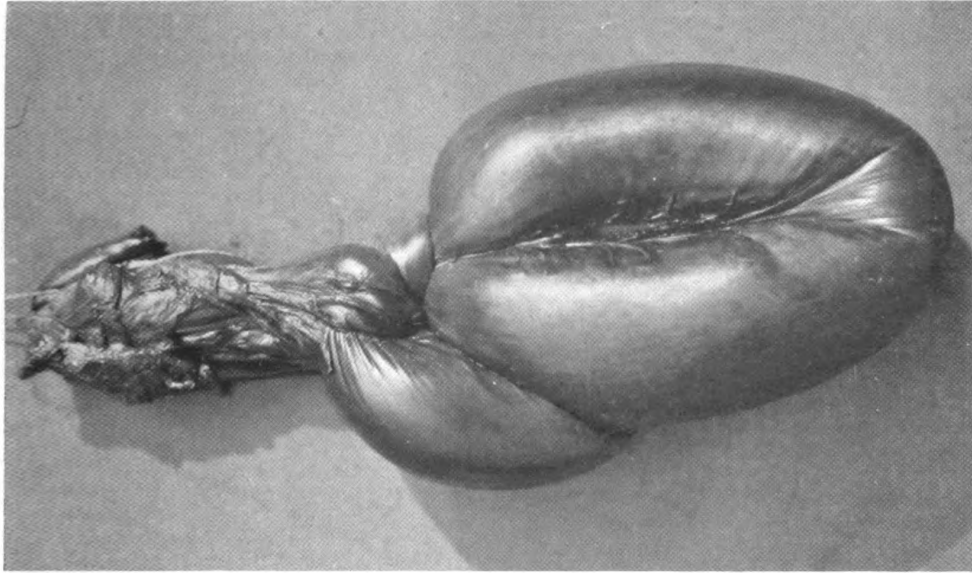

The mare in question, however, although frequently on her back, had very short intervals of rest, the most prominent symptom being that when the poor brute was on her feet she would set her hind legs back and apart, stick up her tail, and throw up her head as if about to urinate. I need not detail the treatment, suffice to say that sedatives per the mouth, skin, and rectum were used, the tympany that was present was liberated twice by the trocar and canula, but without any lasting effect. I told the owner early on that I was afraid the case would prove fatal, and that I suspected the mare was suffering from a twist, or knot, or some other lesion of the bowel, and at 10 p.m. the pulse began to run down and the mare commenced to wander round and round the box, stopping now and again, in fact presenting all the emblems of death, amaurotic eyes, heavy sighing, anxious expression on the face, cold clammy sweat and muscular tremblings. I left about midnight, and the mare succumbed at 2 a.m. The twist is so peculiar I thought it might interest some of the readers of *The Record* if you thought it worthy of production.

HENRY THOMPSON, M.R.C.V.S.

MONSTROSITY.

Now that I have pencil in hand I may as well relate and send photo of a case of *Veterinary Obstetrics*, viz., a double-headed calf, *Dicephalus bi atlanticus* (Fleming), with twisted or doubled spine.

On Wednesday, the 2nd inst., we were called to a cow that was unable to calve, the owner, a man who does a little veterinary work himself, had examined the animal and found that the calf had

VOLVULUS IN A CLYDESDALE MARE.

DICEPHALUS CALF.

Notes by H. Thompson, M.R.C.V.S.

two heads joined together, and he could also find two feet. I accompanied my son, who now does most of this class of work, and ascertained that the calf was a monstrosity (see photo), not only had it two heads but the limbs were crooked and malformed, and the spine doubled upon itself. Ropes were put round the two fore fetlocks, and as luck would have it the cow was well relaxed and roomy, a strong rope was next put round the neck, passing over both heads, and another strong cord was fixed over the left hand head facing, as per photo, behind one ear and through the mouth; when this had been accomplished, the two feet were pressed back and down below the brim of the pelvic bones of the cow and traction laid on the ropes round the neck and head, but the feet rushed forward into the pelvic cavity, which was owing to their stiffness and malformation. As delivery did not seem possible this way, the heads were pressed back again and one of the legs pulled forward and as far out of the passage as possible, skinned, and pulled off by the shoulder, and the other fore leg treated in a like manner, and after the removal of the fore extremities the heads were again brought into the passage and heavy traction applied, the while manipulating with the hands the left hand head was delivered; there was nothing now but strong steady pulling when all of a sudden a loud crack was heard and the foetus came away without any more trouble. On examining the calf afterwards I found that the back was broken in two, behind the shoulder, which accounted for the loud crack. The spine had been doubled on itself, with the malformed hind legs under the body, whilst the walls of the abdomen were open and the intestines outside.

The cow, which is a cross-bred shorthorn, stood the strain splendidly, and after lying for about a quarter of an hour, during which time she drank a pailful of cold water, she got up and commenced to eat some cut green corn, and I am pleased to say she is now going on alright, feeding, chewing the cud, and milking well. The operation occupied about one and a half hours. (Photo by Mr. J. Pattinson).

HENRY THOMPSON, M.R.C.V.S.

Aspatia.

ABSTRACTS FROM FOREIGN JOURNALS.

A CONTRIBUTION TO THE PATHOLOGY OF THE BURSA OF FABRICIUS.

The bursa or pouch of Fabricius is a single organ, which is present in nearly all birds, and lies outside the peritoneal sac between the rectum and the vertebral column. It encloses a cavity, which opens into the cloaca by means of a small canal. In aged birds the organ gradually diminishes in size, till finally it quite disappears. The physiology of the bursa of Fabricius is not explained, and very little has been observed of pathological conditions affecting it. Schautyr and Paukul, who now record

three cases, remark that, so far as they are aware, only two instances of disease of the bursa have hitherto been recorded. Both these were instances of hydropsy of the organ.

The authors' first case was in a hen, whose age was not known, and in whom retention of an egg was diagnosed. During an attempt to relieve this by means of gentle pressure upon the abdominal wall, a bladder-like body of the size of a walnut, and covered with mucous membrane, suddenly issued from the anus. This proved to be an eversion of the pouch of Fabricius, which had arisen from the increase of abdominal pressure upon the organ resulting from manipulation. After the egg had been removed, the pouch was replaced in its normal position by means of pressure with the finger.

The second case was of a seven months old hen, which was said to have laid no eggs for some days, and in which the mucous membrane of the cloaca in the immediate vicinity of the anus was violently reddened. Palpation of the abdominal wall revealed the existence of a body the size of a hen's egg in the region of the pouch of Fabricius. The canal leading from the upper wall of the cloaca into the cavity of the pouch was dilated a little, and the little finger, when introduced into this, encountered a firm mass which was apparently a neoplasm. Small particles of this mass were brought to the air; they were yellowish-grey in colour and granular in appearance, and were easily crumbled between the fingers.

The hen was killed: and a post-mortem examination revealed all the organs normal, with the exception of the pouch of Fabricius. This was round-oval in shape and 2 inches by 1.5th inch in size. The surface was uneven in places, and partially united with the surrounding tissue. The walls ranged from 1-12th inch to 1-5th inch in thickness. The cavity contained a mass consisting of spongy lumps of a yellowish-grey colour, the whole being almost completely separated from the inner surface of the wall of the pouch, and thus easily detached from it. The mass showed, upon section, a more or less clearly apparent concentric structure of its more superficial portions, as if they were composed of single, thin, cup-shaped layers. The central portions, however, had a uniform finely granular appearance.

The authors give a somewhat detailed description of the results they obtained histologically, from which it appeared that the condition was a fibrinous-purulent inflammation of the pouch of Fabricius, with thickening of its walls by an increase of their connective tissue. Staphylococci were found within the mass composing the contents of the pouch; and in all probability the condition had arisen as a result of an infection from the cloaca through the canal connecting it with the pouch.

The third case was also that of a hen, the age of which is not stated. The history was similar to that of the previous case—viz., the retention of the egg; and palpation revealed the presence of a painless, oval, easily movable swelling above the cloaca and the rectum. The situation corresponded to the normal position of the pouch of Fabricius, and a

pathological alteration of this organ was therefore suspected.

The hen was killed, and subjected to post-mortem examination, which revealed no lesions in any organ except the pouch of Fabricius. This had a roundish-oval shape and was surrounded by loose fatty and connective tissue. It was 1-4th inch by 1, 2-5th in size. The surface was smooth, and in parts slightly uneven. In the place of the cavity of the bursa, its interior was completely filled with a tissue of yellowish-grey colour, which blended with the bursal wall without any indication of a boundary between them.

In this case, also, the authors enter, with some detail into the results of their histological examination. This showed that the mass occupying the cavity of the pouch of Fabricius consisted of elements which are characteristic of the lymphatic tissue, viz., lymphocytes and a reticulum. The reticulum was traversed by thin-walled injected vessels, and showed hæmorrhagic infiltrations in places; here and there, also, small necrotic centres were seen. The muscular portion of the wall of the pouch was still demonstrable; but nothing remained of the mucous membrane, which had been completely suppressed and atrophied by the newly-formed lymphatic tissue. The authors regard the condition as a hyperplasia of the follicles which are normally situated in the wall of the pouch of Fabricius.—(*Zeitschrift für Wissenschaftliche und Praktische Veterinarmedicin.*)

W. R. C.

SOME ATYPICAL CASES OF RABIES.

Owing to the extreme practical importance of the consideration of atypical symptoms in canine rabies, I am tempted to record the following cases:—

1. A pointer dog, 12 years old, went out with its mistress on the 4th May; on the 5th there was loss of appetite, vomiting, trembling of the feet; on the 6th and 7th the vomiting continued, and a flow of saliva appeared, food forcibly given was swallowed, the dog could not control the movement of his feet, going round and round for a few steps he fell to the right. On the 8th I was called in, and as I knew its name I called the dog as I entered the room, it approached me lame on its right legs, wagged its tail, and fell, but soon got up again, it went on in a semi-circle but fell after a few steps, again to the right. There was hemiplegia affecting both right legs and the lower eyelid, the eye appearing abnormally large in consequence, the neck was flexed to the right, the tongue was not under control and hung out, pressed by the teeth; and evidently on account of hemiplegia of the pharynx swallowing was difficult, the breathing was hoarse. On the 9th the dog was down, the paralysis had extended to the left legs and jaw which could not be closed, the left eye was normal, the dog tried to rise but could not. When spoken to caressingly it weakly wagged its tail, it trembled a great deal at a sudden noise or unexpected touch.

While being turned over it scratched the arm of its mistress. It could neither bark nor growl, it remained conscious till the night of the 12th, but at four in the morning it was dead.

Post-mortem examination showed empty stomach with patches of congestion, acute congestion of the brain.

A control rabbit inoculated with brain died of typical rabies in fifteen days.

2. Another case of rabies, the paralytic stage of which commenced as hemiplegia. The dog was brought to me as the owner thought it had had a blow on the head, but he did not know when or how, as it had not left the house during the previous day; when I approached the dog it attempted to bite me, although the owner assured me it was not at all savage: the head was turned to the right, and there was a swelling on the left side of the neck, the ear hung down and was powerless, the eye was widely open on account of paralysis of the lower eyelid, and the temporal muscle was swollen as if it had had a sharp blow, but was quite painless to the touch, the neck returned to the right if it was forcibly straightened. As the dog had been unwell for some days—restlessness, want of appetite, etc., I suspected rabies, and advised the dog being isolated, and waited till the next day. In the evening there was paralysis of the hind legs, and later also of the fore legs, complete loss of consciousness, a hoarse bark, biting at the breast walls, etc., and death in the morning.

Post-mortem examination showed the stomach containing splinters, straw, etc., hæmorrhagic patches, full bladder, the swollen parts of the head and neck not congested.

This was the second case of rabies I had seen which commenced with hemiplegia, and the grave significance of this symptom and the absence of others mentioned in the books at my disposal, causes me to call attention to it.

3. Pointer dog, sagacious and well trained, shivered as if cold after passing a cold night out of doors; there was pain in the chest, cough, painful swallowing, flow of saliva, and groaning; during the day the jaw dropped, and there was a thick discharge from the eyes, the pain in the chest decreased, but the jaw was paralysed till the seventh day of the illness, when the dog again was able to close it and there was no other paralysis. During the night of the eighth day the dog as usual woke its master and asked to be let out, it walked out easily and after relieving itself came in again, but in the morning there was tremor of the feet, and soon the dog lost consciousness, paralysis quickly seized the hind legs, and in the evening the front ones also. The dog was tied in a room, and it continually barked and howled. It bit every available object with fury, when a stick was offered to it it furiously snapped at it and broke it to splinters; this furious fit continued from the morning to the night of the ninth day, when it was destroyed as undoubtedly rabid.

I have noticed other cases where the paralysis has not commenced in the jaw and where the power of the jaw has returned. Many authors state that

the non-furious stage of rabies does not continue longer than two to three days, but my experience is otherwise, in my cases it has continued seven to eight days when the furious stage seldom reaches its limit.

I must explain that I am speaking only of those cases established by post-mortem examination and control inoculation; possibly age, size, and place of inoculation modify the conditions, yet I have never seen typical cases of rabies in which the non-furious stage has exceeded five days, and I have seen a two-month puppy dead in two days.

I have noted cases where the incubation period has exceeded 12 days, and in one a big St. Bernard it extended over four months.

For some years I have examined all dogs which have bitten human beings, and last year there was a severe outbreak of rabies in the town.

N. Foss, Govt. V.S., Ufa, Russia.

(From the Author's original esperanto.)

NUT IN A DOG'S INTESTINES.

A small pet dog had suffered for two months from indigestion (vomiting, diarrhoea, loss of appetite, etc.). Then acute vomiting, accompanied by diarrhoea and pain, set in. The owner, a doctor, gave castor oil, which was returned after a few hours, also the water already drunk.

Diagnosis, stoppage of the intestine. Treatment primarily directed to stopping the vomiting. Foss gave opium, and later calomel 0.08 (1½ gr. about) and an enema. The opium stopped the vomiting, and in the morning with the clyster came away a nut in its shell enlarged. The doctor and his wife remembered that the dog while playing two months before had swallowed a nut, which they thought it had passed long ago.

The dog made a good recovery.

F. E. P.

NORTH OF IRELAND VETERINARY MEDICAL ASSOCIATION.

The usual quarterly meeting of this Association was held in Deveney's Chambers, North Street, Belfast, on Thursday evening, August 3rd, at 7 o'clock p.m. In the absence of the President, Mr. J. J. Ross occupied the chair. The following members were present: Messrs. John Ewing Johnston, Howard, McConnell, W. S. M. Smith, Henry Gibson, J. A. Thompson, J.P., and J. A. Jordan.

An apology for non-attendance was received from Mr. John George, Magherafelt.

The minutes of the previous meeting having been read were, on the motion of Mr. Gibson, seconded by Mr. Thompson, confirmed.

At this stage the President (Mr. F. W. Emery) having arrived took the chair.

The SECRETARY, in accordance with request, submitted a copy of certificate granted to Honorary Associates by the Veterinary Medical Association of Ireland, kindly lent by the Hon. Secretary of that Association.

Mr. THOMPSON moved, and Mr. ROSS seconded, that the Sub-Committee already appointed to take charge of this matter be authorised to provide copies of a some-

what similar certificate for this Association, and that they be also authorised to select and order an official seal for the Association. Passed.

It was unanimously agreed that Messrs. J. A. Thompson and Jordan be requested to represent the Association at the forthcoming Congress of the Royal Institute of Public Health to be held in Dublin.

Mr. J. EWING JOHNSTON, in accordance with notice, moved that a sum of £4 4s. be allowed to the Hon. Sec. annually in order to provide an assistant. This to take effect from the 1st January, 1912. After discussion this was passed.

It was decided to hold the November meeting in Ballymena on Thursday 16th.

A renewal of the discussion on the question of amalgamation took place, when Mr. Johnston moved, and Mr. Gibson seconded, that this Association approve of the scheme proposed by the Committee of the National Veterinary Association.

Mr. ROSS proposed as an amendment that the matter be deferred until the return from Dublin of Messrs. Thompson and Jordan, when more definite information might be forthcoming. This was seconded by Mr. McConnell. The amendment having been put to the meeting was carried.

Mr. H. D. GILMORE, Kirkecubbin, had kindly consented to read a paper entitled "Notes on a Few Cases," at this meeting. The Secretary, however, announced that he had received the following wire from Mr. Gilmore:—"Owing to accident deeply regret inability to attend meeting."

On the motion of Mr. ROSS, seconded by Mr. McConnell, the Secretary was requested to send a letter of sympathy to Mr. Gilmore. Passed.

After the usual vote of thanks to the President, the meeting terminated.

J. A. JORDAN, Hon. Sec.

SOUTH DURHAM AND NORTH YORKSHIRE VETERINARY MEDICAL ASSOCIATION.

Acting upon the suggestion of the President (Mr. G. R. Dudgeon) given in his Presidential address, that one meeting during his year of office should be of a social character, it was unanimously agreed at a meeting of the Association held on July 7th that an excursion should take place to Middleton-in-Teesdale and Langdon Beck, and a small sub-committee was appointed to make the necessary arrangements. This excursion took place on Friday, July 28th, in perfect summer weather, and it was indeed a happy party of members and their lady friends numbering twenty that left Darlington by the 10.28 a.m. train in a reserved saloon for Middleton-in-Teesdale, which was reached about noon. The members were sternly informed by the President that anybody talking "shop" would be fined five shillings for each offence, and his wishes that professional duties should be left at home were rigidly adhered to for the rest of the day.

On arriving at Middleton-in-Teesdale brakes met the train and conveyed the party to "Ye Cleveland Arms Hotel," where an excellent dinner was partaken of, the worthy President being in the chair.

Previous to dining the church was visited, and through the kindness of the Vicar, who was known to one of the members, an invitation was given to visit his garden, which was much appreciated, lovely views of Teesdale being obtained from it.

After dinner the company was photographed, but owing to the fierce rays of the sun the expression on the faces of many was not considered all that could be desired when the proofs were inspected later on in the

day, many of the ladies appearing rather disappointed that their undoubted beauty of features had not been more clearly brought out.

The brakes were again boarded, and the drive up the beautiful dale resumed. The eight mile drive up to Langdon Beck was perfect, the well kept farm houses, newly whitewashed, on the estate of Lord Barnard, forming a pretty picture against the rich green of the pasture and meadows where haymaking was in full swing, whilst on the Yorkshire side of the dale the outline of the grand hills was clearly defined against an almost cloudless sky, as there was a cool refreshing breeze everything that was to be seen was seen to perfection. A call was made at High Force to view the renowned waterfalls, and as there was a nice volume of water passing over them one saw them almost at their best.

On arriving at Langdon Beck Hotel the more energetic of the party indulged in the old-fashioned game of "rounders" which caused much merriment, and also revealed the fact that one or two of the players were not so sound in their wind as they were twenty years ago, suspicious sounds of "whistling" being heard.

Tea was then partaken of, the bracing moorland air having sharpened the appetites of all. The return journey was commenced about 6.30 just as the sun was setting behind the hills, the beauty of the western sky will not readily be forgotten.

On arriving at Middleton-in-Teesdale complimentary votes of thanks were passed to the President and Sub-Committee for having arranged such an enjoyable outing, all agreeing that this, the first excursion of the Association, had been a huge success, and hopes were freely expressed that a similar excursion should be arranged each year.

Darlington was reached about 9.30 the party then breaking up and going to their respective homes by train or motor car, only sorry that the day had passed all too quickly

J. H. TAYLOR, Hon. Sec. (*pro tem.*)

MIDLAND COUNTIES VETERINARY MEDICAL ASSOCIATION.

The quarterly meeting was held at the Grand Hotel, Birmingham, on Wednesday, August 9th. The President of the Association, Mr. H. L. Pemberton, of Bridgnorth, took the chair, and there were also present Messrs. J. J. Burchnall, Barrow-on-Soar; R. Over, A. Over, Rugby; H. Thackeray, Stafford; W. H. Brooke, Handsworth; W. T. Brookes, Warwick; S. D. Woodward, J. Young, W. J. DeVine, C. J. Byner, Birmingham; Parsons, Cheltenham; J. Martin, Wellington; W. Tart, Longton; H. Collett, West Bromwich; J. A. Gold, Redditch; and the Hon. Sec., Mr. H. J. Dawes, West Bromwich.

The visitors present were Messrs. Stewart Stockman, Chief Veterinary Inspector of the Board of Agriculture; H. W. Dawes, West Bromwich; and E. M. Robinson, Kidderminster.

Apologies for unavoidable absence were received from Professors McCall, Dewar, and Hobday, Messrs. E. O'Neill, Ramsey, F. W. Barling, H. B. Hiles, E. Woodcock, J. R. Carless, R. Cockburn, D. Forwell, P. Woolston, Barton, T. H. Hobson, R. C. Trigger, W. H. Brown, J. W. Coe, E. Ringer, F. V. Steward, W. Grasby, H. S. Reynolds, R. Hughes, L. W. Heelis, and others.

The minutes of the previous meeting were read and confirmed.

NOMINATION.

Mr. B. L. SECKER, of Malvern Links, was nominated for membership of the Association by the Hon. Sec., on behalf of Mr. F. W. Barling, of Ross.

RECOMMENDATIONS OF COUNCIL.

The HON SEC. reported that a meeting of the Council was held immediately prior to this quarterly meeting, Mr. J. A. Gold being voted to the chair in the President's temporary absence. There were also present Messrs. Martin, R. Over, Brooke, the Hon. Treasurer (Mr. Burchnall), and the Hon. Sec. (Mr. Dawes). It was recommended:—

(1) That the next quarterly meeting be held at Leicester.

(2) That the subject for discussion be "Clinical Notes on Cases by Members," the Hon. Sec. to circularise members to ascertain how many will be able to contribute to the proceedings and in what way.

(3) That the invitation to be represented at the annual Congress of the Royal Institute of Public Health at Dublin be declined for this year.

On the motion of Mr. A. Over, seconded by Mr. Woodward, the report of the Council was adopted, and the recommendations contained therein agreed to.

THE LATE MR. W. CARLESS.

The HON. SEC. said that since their last meeting they had lost one of the oldest and most respected members of the Association in the person of Mr. Wm. Carless, of Stafford. He always took the liveliest interest in the welfare of the Association, and no one was more regular in his attendance. He was president as long ago as 1883 and since then he had served the office of treasurer. He (Mr. Dawes) was looking through the minutes a few days ago and read the presidential address which the late Mr. Carless delivered when he was in the chair, and it was one of the ablest and most practical that had ever been given. Some of them would remember the Midland Veterinary Debating Society which met once a month for several years, and Mr. Carless came regularly to all the meetings and was most helpful, especially to those of the younger members who had gone to learn. They would all miss him very much and he begged to move that they record their deep sense of his loss, and tender to the family their sincere and respectful condolences.

The PRESIDENT, in seconding, said he had known Mr. Carless for many years as an upright and honourable member of their profession, and one moreover who had a sunny disposition and the happy knack of making friends.

The motion was carried *sub silentio*, the members signifying their assent by standing.

"THE EPIZOOTIOLOGY OF ANTHRAX."

By STEWART STOCKMAN, M.R.C.V.S.

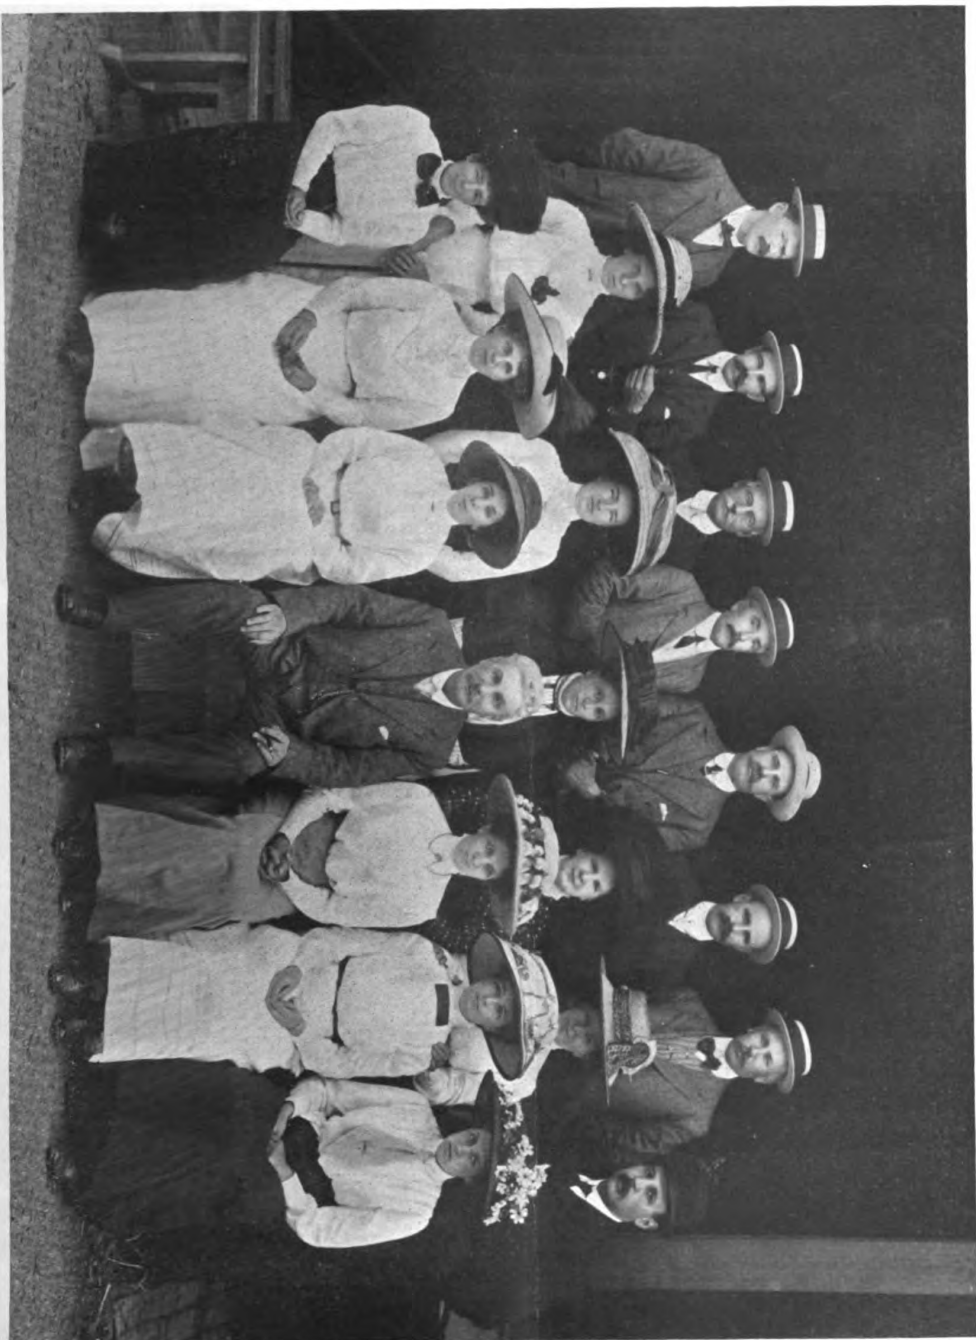

[Read before the meeting at Wolverhampton on May 9th.]

When I was invited to read a paper on anthrax I was very considerably informed that I might choose for my paper whatever features of the disease I preferred to deal with, for it is evident that anthrax in all its features cannot be dealt with in one lecture. I have chosen the epizootiology of anthrax, and, as diagnosis and prevention are most important parts of epizootiology, I have attempted to deal with them as fully as possible.

DIAGNOSIS.

In the cases of cattle and sheep the usual history is that one animal has been found dead or in a moribund condition, and that signs of serious illness had not been observed until shortly before death. Anthrax may or may not be suspected by the owner. Anthrax, however, is not always fatal, and inasmuch as several animals may have contracted the disease from the same source, and be less severely attacked, or in different stages of the disease, it is advisable to make use of such clinical aids

The Veterinary Record, August 19, 1911.

SOUTH DURHAM AND NORTH YORKSHIRE V.M.A. AT MIDDLETON-IN-TEESDALE.

to diagnosis as can be applied on the spot to animals in contact. This applies especially to cows in byres, and it has frequently been observed that some of the contacts to an animal which has died of anthrax show a suspiciously high temperature.

In the cases of horses and pigs there are often certain objective symptoms to guide one, such as swelling of the tissues around the throat, and in the former severe colic. These external lesions are of great value in connection with diagnosis during life and after death, but, while their presence is strongly indicative of anthrax, their absence cannot be regarded as satisfactory evidence that the disease does not exist.

The irrefutable evidence of the existence of anthrax is the presence of the anthrax bacillus in the body fluids or tissues. The blood is the fluid from which preparations can be most conveniently made for microscopical examination, and, since the bacilli seldom invade the blood stream in sufficient numbers to be detectable until the animal is practically moribund, a positive diagnosis follows usually upon the finding of anthrax bacilli in the blood after death. It is seldom indeed that the bacilli have not invaded the circulation in large numbers in cattle and sheep just before death, but very occasionally cases of anthrax are met with in these animals in which a microscopical examination of blood from the peripheral vessels fails to reveal the presence of anthrax bacilli, and other methods of diagnosis have to be employed. In pigs and horses it frequently happens that the animals die of anthrax before the bacilli have invaded the circulation in large numbers, and under such circumstances diagnosis by the microscopical examination alone of smears from the blood in the peripheral vessels often fails. It is advisable in horses and pigs to make smears from a gland near the surface, and from any oedematous fluid which may be present, as well as from the blood.

Given that these methods of examination have been applied with a negative result, there is nothing left except to seek for the cause of death by an examination of the internal organs, still paying due regard to the possibility of anthrax existing, and taking all reasonable precautions against infective material being disseminated. A great deal of importance is often attached to finding a carcass of an animal tympanitic, with blood oozing from the orifices. Without wishing to minimise the importance of this in arousing suspicion of anthrax, I would like to remark that no conclusion can be drawn from its presence or absence. It may happen that this further examination will tend to increase one's initial suspicions. For example, if enlargement of the spleen be found, with a fluid tar-like appearance of the pulp, or if the intestines and lymph glands are markedly congested, anthrax should always be suspected, and smears for further microscopical examination should be made from the altered organs.

A fairly common lesion in pigs, and one of great diagnostic value, is the presence of necrotic areas on the mucous membrane of the pharynx. These vary in size, but are commonly as large as a shilling. The centre is dark, almost black in colour, slightly raised, and the edges are level with the mucous membrane. There is seldom any difficulty in finding anthrax bacilli in preparations made from these areas.

In cattle and sheep anthrax may be confused with black-leg. The local lesions of the latter disease are generally sufficient for differential diagnosis, but it must not be forgotten that in sheep dead of black-leg lesions of the skeletal muscles may be very slight, or even absent. It is sometimes stated that the bacillus of black-leg does not invade the blood stream. This, however, is an error, and the finding in almost pure culture of an appreciable number of bacilli like those of black-leg in preparations made from the blood is almost sufficient evidence to exclude anthrax. In the horse one

may be misled during the life of the animal by the belief that it is suffering from serious intestinal trouble. In dealing with the carcass of an animal, however, it is unnecessary to attach a great deal of importance to differentiating finely between the macroscopic lesions of anthrax and other diseases, because if the circumstances or lesions are such as to make one suspect anthrax the question can be decided by establishing the presence or absence of a definitely ascertained microbe; these things are happily no longer the matters of opinion which men of the more ancient clinical school found time to wrangle about.

We have next to consider the methods of establishing the presence of anthrax bacilli in fluids and tissues, and microscopical examination naturally comes first for consideration. I take it, it may be assumed that everybody knows what is meant by a smear, that smears should be made from blood present in the peripheral vessels, such as those at the base of the ear, that they should not be made from blood found oozing from the orifices, that in the cases of the horse and pig it is highly advisable also to make smears from a superficially placed lymphatic gland, and that for bacteriological examination an oil immersion lens is indispensable. The smears are fixed by heating the glass slides over a flame, after the fluid has been dried. Amongst the specimens sent to the laboratory purporting to contain anthrax bacilli a few have been unstained cover-glass smears of blood mounted in balsam, and I have known members of our profession who claimed that they had no difficulty in identifying anthrax bacilli in unstained preparations. This, however, is rapidly becoming a lost art, and one of the penalties we have had to pay for the advance of civilisation is that we must now stain our anthrax preparations. The anthrax bacillus is not difficult to colour with any of the bacterial stains, nor is it difficult to identify whatever be the stain employed, provided the material for the smear has been obtained very soon after the death of the animal and the organisms are fairly numerous. The classical description of the anthrax bacillus in preparations from the blood is: a rod-shaped organism measuring 5 to 8 μ by about 1 to 2 μ , ends square cut, or showing cup-shaped depressions, consisting of a central rod of protoplasm bounded by a translucent capsule, occurring singly, or in twos or threes joined end to end, but not as long filaments. To see anything very closely resembling the above picture, one must examine perfectly fresh material taken soon after the animal's death. If one expects always to find it in preparations made under the conditions obtaining in the field of practice, the expectation will not be realised. The veterinary inspector frequently does not arrive on the scene until twenty-four or thirty-six hours, or even more, after the animal has died, and it is common knowledge that in this time even the blood in the peripheral vessels may become grossly contaminated by the organisms of putrefaction, especially during hot weather. These organisms, as it were, crowd out the anthrax bacilli, and as some of them, particularly the bacilli of malignant oedema, bear a certain resemblance to anthrax bacilli, the problem of identification becomes more complicated. Further, it is also well known that anthrax bacilli contained in blood, especially under the anaerobic conditions obtaining in the blood vessels of an unopened carcass, undergo degenerative changes, and disappear in a variable time. These changes give rise to distorted forms, which, up to a certain point, may aid identification, and beyond that make it more difficult. The central protoplasm may be twisted, shrivelled, and very granular, but the most marked changes are probably observed in connection with the capsules, which may swell up to several times their original size, and assume curious shapes; they may also rupture. Sometimes the protoplasm inside the swollen envelope takes the stain very feebly, giving rise to what may be referred

to as ghost forms. In preparations made from tissue which has been exposed to the air for some little time one may also see anthrax threads of considerable length, made up of bacilli of about equal length joined end to end, and there may even be sporulating forms in warm weather. In the majority of cases, however, the long forms seen in preparations are not anthrax filaments; they are threads of the malignant oedema bacillus, made up of rods of very unequal length, and of greater thickness than those of anthrax when stained in certain ways. Other filaments of bacilli more or less resembling anthrax may also be present when the material has become grossly contaminated.

I have purposely said nothing about motility as an aid to differentiating between anthrax and other micro-organisms, as I consider the manipulations necessary to put it in evidence are too dangerous to be made use of by practitioners. The anthrax bacillus is not motile.

Two methods of staining are particularly helpful in the identification of anthrax bacilli, while certain others should be avoided. First, we may take Gram's method. This is not a good method for staining the anthrax bacillus, as it usually shrivels the protoplasm, renders it very granular, and causes a certain amount of distortion, which may make identification somewhat difficult in certain preparations. On the other hand, it may be usefully employed, when necessary, to distinguish between the anthrax bacillus, which is Gram-fast, and other somewhat similar microbes which are not—malignant oedema, for example. The most misleading stain of all is gentian violet, which is apt to colour the envelope of the anthrax bacillus, giving the rod an unnaturally thick appearance. This increases the difficulty of distinguishing between it and certain other microbes. The now well-known methylene-blue method of staining has the highest diagnostic value of all. As everyone knows, this, as a valuable aid to the identification of anthrax bacilli in preparations made from the blood, was first described by Sir John M'Fadyean. It consists in staining the smears in a 1 per cent. watery solution of methylene blue, and an essential point in the technique is that the smears must be only lightly fixed. The protoplasmic rod stains blue without undergoing distortion, and the capsule, particularly if it has become swollen, takes on a rose-pink colour. Sometimes the material of the capsule becomes massed, and appears in the preparations as small pink islands; at other times the field of the microscope has a pink, peppery appearance. Even after all the rods have disappeared one can often find pink masses in a blood smear.

In my Annual Report for 1905 certain observations on guinea-pigs dead of anthrax were described, in which the pink reaction was obtained eighty-six hours after death, but was not obtainable 126 hours after death, when the body had been opened; and in another guinea-pig, which had not been opened, a very distinct reaction was obtained in preparations made from the spleen ninety-six hours after death. Since then I have obtained it from scrapings of dried blood from a shed in which the carcase of a cow dead from anthrax had been dressed about a month previously, and I have also obtained it from the spleen of a cow which was exhumed three weeks after death. I do not, however, mean to assert that one can count upon obtaining it at these long intervals after death.

The other aids to diagnosis which one may employ are cultural examination and inoculation. These are methods for the laboratory, but, inasmuch as the laboratory has to depend on the practitioner for material, you will probably desire that I should say something about these methods, and how material should be collected for transmission. When the microscope fails to reveal the presence of anthrax bacilli, or when the material is so grossly contaminated with other microbes that identification of the anthrax bacillus is difficult, inoculation or

cultural examination may be resorted to, and it ought to be made use of if the history of the case is suspicious. For inoculation guinea pigs or white mice are usually employed, and one is almost always restricted to the scarification method in order to avoid killing the animals with malignant oedema. Material which is grossly contaminated, or which contains very few anthrax bacilli, sometimes fails to infect by the scarification method, and on this account it seems probable that the cultural method is the more reliable, because the contaminations can be got rid of, and there is no reason to believe that one or two bacilli or spores are not sufficient to start a culture, although they may fail to fatally infect an animal. Agar slopes are inoculated with material from a swab, and placed in the incubator overnight to give any anthrax bacilli which may be present the chance to sporulate. The culture tubes, or material therefrom, are heated in a water bath at 80°C. for half an hour. This kills all the non-sporulating bacteria, which are the majority, and by making cultures on agar slopes from the heated material it is possible to obtain relatively pure or even pure cultures of the anthrax bacillus in a matter of hours. Needless to say, the material sent to the laboratory should be collected as purely as possible.

What is now known as the Strassburg method of collecting material has been strongly recommended by many authorities. In this method pieces of gypsum are soaked in broth, which fills the pores, and they are afterwards sterilised in test tubes and sent out to inspectors. The gypsum is dipped in the suspected material and returned to the laboratory. The theory underlying this method is, that the anthrax bacillus finds the conditions for sporulation in the pores of the gypsum, assuming the temperature to be favourable, and may even have sporulated by the time the material reaches the laboratory. Under the conditions prevailing in Great Britain, however, the simpler method of sending to the laboratory smears and a swab of sterile cotton-wool which has been soaked in the suspected material meets the case. This is the method in use by the Board of Agriculture, and I have brought with me an apparatus which has been designed for collecting and transmitting material.

Members of this Association will probably be surprised to learn that at this late date in the history of a profession which may justly claim to be a scientific profession, there are still men in the position of veterinary inspectors to Local Authorities who are so forgetful of their responsibilities as to send by post, in cigar boxes and other leaky vessels, portions of spleen and other tissues from animals suspected of having died of anthrax. Apart from the moral obligation involved, I think you will agree with me that it would not advance the prestige of the veterinary profession if any one of its members had to answer a charge of contravening the Post Office Regulations in a matter of this kind, or if he were charged with the more serious offence of culpable homicide.

EPIZOOTIOLOGY.

The most important factors admitted or suggested to explain the upkeep and dissemination of anthrax are as follows:—

First. The disease is not disseminated to any important extent by the infected animal during life, but it may arise from a patch of infection established by a previous case on a pasture. It is well known that anthrax bacilli may sporulate under certain conditions, and that the spores are very tenacious of life; in the laboratory they may remain infective for several years. One does not know definitely, however, to what extent spore formation may occur in blood, etc., deposited on the pastures under the climatic conditions obtaining in Great Britain, and it must be remembered that for several years past it has been customary to avoid the spilling of blood from

animals dead of anthrax. Nor is it known how long the spores of anthrax, granted their formation, may remain capable of infecting after their arrival on the pastures. The available evidence is totally opposed to the view that anthrax arises mainly, or even to a great extent, from previous cases on the same establishment. If it did, one might fairly expect to find the disease frequently repeating itself on the same establishments in the same year and from year to year. This does not happen in Great Britain. The information summarised in Table I from the official records clearly shows that the vast majority of outbreaks (average 83.5 per cent.) occur on farms which have not been previously infected, and it is to be noted that it does not necessarily follow that in the remainder (16.5 per cent.) infection arose from virulent material on the pastures, or from a previous case on the same establishment.

TABLE I.

Showing Total Outbreaks for Five Years—1902-1906—in six of the Worst Infected Counties in Great Britain, together with the Number and Proportion of Outbreaks on New and Previously Infected Farms

County.	Total Outbreaks.	Number on new Farms	Per cent. of Total.	No. on previously Infected farms	Per cent. of Total.
Aberdeen	500	400	80%	100	20%
Somerset	143	119	83%	24	16%
Salop	125	112	89%	13	10%
Wilts	78	67	80%	11	19%
Cheshire	218	191	87%	27	12%
Total	1064	889	83.5%	175	16.5%

By going through the records in the above counties of the 993 farms infected for the first time during the ten years from 1895-1904, I found that anthrax had occurred more than once during that period on 120 farms, that is, on only 12 per cent. of the total.

With regard to the proportion of farms on which anthrax occurred more than once in any one year, the records over a period of twelve years (1895-1906) for the above counties were examined. There were infected for the first time during that period 1388 farms, and anthrax occurred more than once in any one year on only fifty of them (4.6 per cent.) These figures were published in my Annual Reports for 1905 and 1906, and since then the records for all the other counties of Great Britain have been examined with practically the same result. In considering the importance of ground infection one must also weigh the fact that although there have been over 500 outbreaks a year in Great Britain for many years, which must have infected an enormous number of premises, the disease has certainly not increased in proportion, and only a small minority occur on previously infected farms.

Table II. shows the quarterly incidence of anthrax from 1906-10. It will be observed that there is a marked and constant drop in the number of outbreaks in the third quarter of each year, that is to say, at the time when most stock are on grass, and that there is a decided rise when the animals may be assumed to be running in, and receiving artificial food.

Second. It is suggested that the disease is carried by flies.

Many are familiar with the sight of flies feeding on the blood of a carcase which has been opened, and one of the oldest suggestions in relation to infection in the case of anthrax is that it may be carried by flies. In a

recent report to the Local Government Board, Dr. Graham-Smith showed that living anthrax bacilli could be recovered from the material which flies regurgitate after feeding, and from their faeces, provided they had fed on anthrax bacilli. Cultures were obtained from the faeces forty-eight hours, and from the crop five days, after feeding. After feeding on spores cultures were obtained up to the twentieth day. This, of course, is not surprising, as we know the spores may live for years. These observations convey the suggestion that flies in the above way disseminate anthrax. I think one must admit that flies could carry infection, but, interesting as Graham-Smith's observations undoubtedly are, there is no important gap in the epizootiology of anthrax which his observations can fill. Further, we have every year a certain number of cases in which men contract anthrax from dressing infected carcases. When this happens it is not those helping, on whom flies may, and do, alight, who contract the disease, but almost invariably it is the man who does the actual cutting, and who has sores on his hands and arms, which come in contact with the blood. Moreover it is quite obvious from Table II. that the number of outbreaks in cattle drops very decidedly during the season in which flies are prevalent.

Third. Infection may be carried by contaminated feeding stuffs brought in from without, particularly by material brought in from countries where anthrax is very prevalent.

The facts brought out in Table I. are strongly in favour of the view that the great majority of outbreaks in this country are due to infection from without. Table III. summarises the information collected in connection with 1257 outbreaks of anthrax on previously clean farms, where ground infection could not have operated. It is to be observed that only those cases in which the diagnosis was beyond question have been taken, and that special inquiries were instituted into the correctness of the history of the premises.

TABLE III.

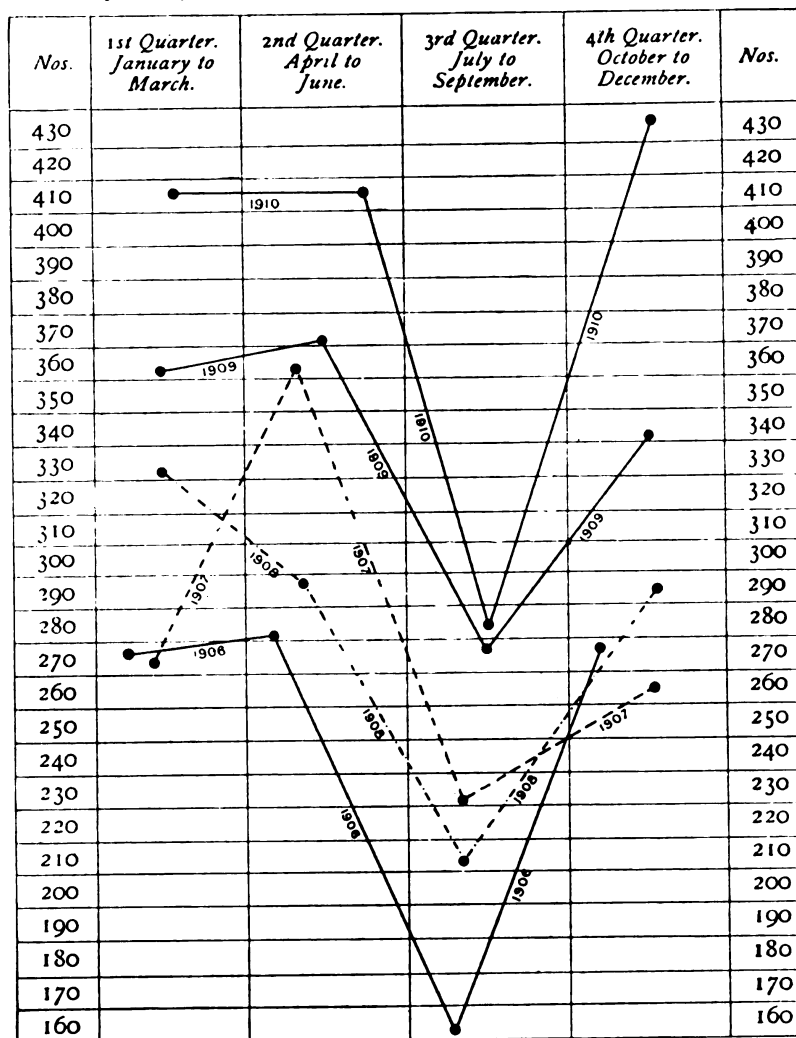

Showing Results of Special Inquiries into Cases of Anthrax reported from Farms said to be Infected for the First Time (1905, 1906, 1907, 1908, 1909).

Total cases inquired into 2527. Deduct 1270 cases in which the diagnosis could not be confirmed = 1257.

Confirmed cases. Total	1257
Number of those which on further inquiry might have been due to a former case (i.e., a death under suspicious circumstances was known to have taken place).	179 (14%)
Number of those in which no former history of Anthrax could be obtained after careful inquiry.	1046 (83%)
Number of those in which after careful elimination of other causes the evidence pointed to artificial feeding stuffs or manures	860 (68%)
Number of those in which there was no history of former outbreaks nor of artificial feeding stuffs nor manures	254 (20%)

Evidence that food stuffs carry infection is very difficult to obtain under the conditions of experimentation, one reason being that the infected portions have probably been consumed by the dead animal before samples were taken. During the last few years samples of feeding stuffs upon which suspicion rested have been experimentally examined at the Board's laboratory with negative results. Both Sir John M'Fadyean and Mr. Dunstan, M.R.C.V.S., however, have demonstrated experimentally that cake may contain the spores of anth-

TABLE II.
Quarterly incidence of Anthrax in Great Britain, 1906-1910.

rax, and the former has isolated the anthrax bacillus from imported oats. These positive results, few as they are, are of the highest importance to the question under discussion, when one considers how enormous are the chances against obtaining them with the small samples it is possible to examine experimentally.

One has next to inquire how feeding stuffs may become contaminated. In the process of manufacture the material from which cake is made is heated to a temperature considerably below the boiling point of water (180 to 200 F.), which is, of course, insufficient to destroy the spores of anthrax. Compound cakes are pressed between metal plates, but the seed from which the other cakes are made is pressed in cloth bags, made from refuse wool and horse hair, to extract the oil. On the assumption that the material used in the manufacture of bagging might infect the cake (shoddy wool and horse hair are frequently infective), about a hundred different samples were examined experimentally at the Board's laboratory, but with negative results. Personally, although I cannot free my mind from the the suspicion that bagging may infect cake, I think the most

likely explanation of infection is that the grain or meal in course of transit from countries badly infected with anthrax becomes contaminated by infective material from dry hides, which, on account of their light weight, are often stowed on the top of other cargo. I have known a number of outbreaks follow the distribution of a consignment of Soya beans in a part of the country where previously anthrax was almost unknown. It should also be noted that there is a possibility of cake being contaminated by infected material after it leaves the factory.

Fourth. Infection may be disseminated by bone manure, shoddy manure, and refuse from tanneries, which may be put on the land or allowed to contaminate the water supply.

There is no doubt that the disease is exceptionally prevalent in certain districts where imported hides are tanned and wool is washed, the assumed explanation being that the drinking water becomes contaminated by the sewage from the factories. In the course of inquiry it has also been found that the disease is exceptionally prevalent on certain sewage farms which are known to

receive tannery and knackery drainage. With regard to bone manure, I have not obtained evidence that a large number of outbreaks can be accounted for in this way, and it should be noted that most of the bone manure used in this country has been heated, or submitted to a chemical process amounting to disinfection, before it is used on the land. There are outbreaks, however, in which the circumstantial evidence indicates that infection has been introduced with turrips which have been grown on land manured with crushed bones. Given infected particles of bone in the soil, one can imagine that roots with the earth adherent might be infective.

PREVENTIVE MEASURES.

In discussing preventive measures in relation to anthrax, I would like to take further advantage of the liberty you have accorded to me of limiting discussion on my part to certain features, for it would not be possible to deal with every side of this question without prolonging the paper beyond reasonable bounds, and I feel I have already overstepped the limits of your patience. I would like to restrict myself to preventive and curative inoculation, as the part of the subject which is of more direct interest to practitioners.

The Pasteur method of preventive inoculation has rendered great service in preserving stock on badly infected farms in various parts of the world. The method consists in injecting the animals with fixed doses of attenuated cultures of the bacillus anthracis. Two injections at intervals of twelve days are performed. For the first injection a very attenuated culture is used (first vaccin), and for the second a less attenuated culture (second vaccin) is employed. Immunity is established about twelve to fifteen days after the second vaccin has been injected. It lasts in cattle about a year, and should be repeated after this period. The great majority of cattle operated on show little more than a temporary indisposition with passing fever after the injection, which may be assumed to indicate a slight attack of anthrax. Occasionally, however, an inoculated animal may die of the disease as the result of the injection, and for this reason the animals undergoing the process of immunisation should be kept in a special paddock, or, better still, in sheds which can be disinfected in event of an accident taking place. In sheep, accidents are more frequent. The operation should only be attempted by skilled persons, who will know the best way to prevent accidents, and adopt measures to limit their consequences should they occur.

Since the operation is not altogether unattended by the possibility of loss, and since it incurs a certain amount of expense, one has to consider under what circumstances it will be worth while undertaking it. It will be obvious from the first that on farms registering only one death annually it will hardly be called for, and that it would be folly to adopt it on clean farms.

It results from observations on several millions of cattle in various parts of the world that accidents occur in about 5 per cent, of the inoculated taken all round, and that the operation may be expected to reduce the death-rate from anthrax on infected farms to about 1 per cent, or slightly under.

If accidents threaten to occur from the inoculation, they can be avoided to a large extent by giving a dose of anti-anthrax serum. This serum is useful both as a preventive and as a curative agent under certain circumstances. The immunity following upon an injection of serum is, of course, quite temporary, but it lasts long enough to tide the animals over certain risks. For example, if an animal has died from anthrax amongst other animals and its blood has been spilt, it is advisable to inject the others with serum, and remove them from the infected place if possible. If it is not possible to remove them, it is even more desirable to give each a dose of serum to protect them while disinfection

is being carried out. The immunity from serum lasts about ten days. When a case of anthrax has occurred, from infection by cake or from preventive inoculation with virus, for example, and any of the animals in contact show an abnormally high temperature, a dose of serum should be injected. Unless an animal has been very heavily infected, which does not frequently happen in practice, the infection remains local for a long enough period to enable serum to act.

The chances are very much in favour of saving the life of the animal by the use of serum, provided the blood-stream is not yet invaded by the bacilli. Once the blood-stream is invaded, serum is likely to fail.

PHYSIOLOGICAL PRINCIPLES OF PHYSICAL TRAINING.

By M. S. PEMBREY, M.A., M.D.

[Being a lecture delivered to the Sanitary Institute, May 3rd, 1911].

At the present time there is a widespread interest in systems of physical training. This is both a good and a bad sign: good, because it shows the recognition of the need of improvement in the physique of the people; bad, because it proves that the natural instincts which once guided mankind are becoming lost in the progress of civilisation. Compulsory education has enabled all to read, and nowadays no one can escape reading in the newspapers something of the promises made by the inventors of so-called scientific systems of training. It would appear, from many glowing accounts and testimonials, that almost every disease can be cured by a course of special exercises. Many readers are misled, for they think that they are studying science when they gaze upon crude diagrams of the human frame, and read the anatomical names of different parts.

It would be far better if more attention were paid to the teachings of instinct, common-sense, and experience. Anatomy deals with the structure of the dead body, and can never supply knowledge of the processes which occur during life; it can never be made the basis of any true system of physical training. The first principles must be biological.

At the very beginning of their existence animals have a potential fitness for some special mode of life; some will become swift runners, others climbers, and others fliers. As they grow they acquire a physical fitness which excites our admiration, and we may well ask how the swallow learnt to fly, or the waterfowl to swim and dive. Here no system of physical training has been handed down by tradition. The opportunity for exercise is all that the animal requires. In healthy young animals, as in children, is inherent the love of games and romps. At first they move in a clumsy and ill-timed manner, but soon they learn by frequent practice how to regulate the sequence and force of the contractions of their muscles. They are not taught by their parents, they learn by themselves, and by their gambols train themselves for the work of their life. Their physical training progresses with their age.

In games, therefore, we can find a natural basis for the physical training of the young. We must accept the teaching of evolution and be guided by experience, for our knowledge of anatomy and physiology in relation to muscular work is too incomplete.

An attempt will now be made to show how much we can learn about the physiological principles of physical training when we examine carefully the experience which has been obtained from games, sport, and work. The first principle is progression. The early practice for a contest is made easy and of short duration, and by gradual stages the subject learns to accommodate him-

self to more and more severe work. The value of progression is recognised by all athletes. The first performance of a definite muscular action is not so economical as the later ones; some muscles are contracted unnecessarily, others are contracted out of their proper sequence, and undue fatigue and soreness are produced. Practice makes perfect, and each man develops as his own the style which best befits the capacities of his body. The authors of systems of physical training insist upon the proper style in which a given exercise should be performed; herein they make a mistake. There is no uniformity in style, and the results of numerous contests on land and water have proved the importance of individuality. No two men are constituted in the same way, and they will not perform a given piece of work in the same way.

Different games, sports, and work require special developments of different muscles. Progressive training produces the necessary effect; muscles respond to work by increased activity and growth. Gymnastic systems lay great stress upon the uniform development of all the muscles. This is uneconomical; no one can become proficient in all forms of work, and a great development of muscles which are not required, is a drawback, producing slowness of movement, a condition known as "muscle bound." If all the muscles are to be uniformly developed, they must be constantly used, otherwise some will atrophy from disuse. So-called uniform development may produce an ideal figure, but the test is not how the man looks but what he can do. The ideal figure is, moreover, a convention, and the fashion changes. At one time the gymnastic ideal produced the soldier with the "pouter chest"; his fitness was sacrificed to appearance. At another time the "strong man" of the music halls was the type, and alertness of mind and body was of little value compared with enormous muscles.

Gymnastic ideals come and go, but nevertheless they do harm. Not long ago it was maintained that during walking and marching the arms ought not to swing with the stride; this was opposed to all physiological knowledge and experience, caused a waste of energy, and impeded the circulation of the blood in the arms.

Uniform development and action are contrary to all we know of division of labour and differentiation of structure. A farm labourer who would march across a ploughed field with the step of a gymnastic instructor is a fool. He does not do it, for he has learnt by experience the gait which is most economical and comfortable. A healthy man who has to carry loads upon his shoulders develops a figure most suitable for his work, even although it is opposed to all the ideals of the gymnastic expert. The test of lifting and carrying sacks of corn will show who is right. Individuality ought to be cultivated, for uniformity results only in degeneration. Games favour individuality; gymnastic systems deadly uniformity.

Muscular exercise influences the whole body, and the different organs react upon each other. It will be convenient, however, to consider the different systems of the body in relation to physical training.

The *Heart and the circulation of the Blood* must be regarded as the most important factor. A great athlete must have a good heart, but he may have but little mental capacity. The heart pumps the blood through the lungs, and is the most important component in a "good wind," for it is useless to ventilate the lungs unless the blood circulates rapidly enough for the efficient removal of carbon dioxide and the necessary absorption of oxygen. One erroneous idea of some authors of systems of physical training is the expansion of the chest in order to give the heart more room in which to move during work. Their little knowledge of anatomy and physiology has led them astray, for they have forgotten that a vacuum cannot be produced in the chest.

Athletes and the trainers of racehorses and greyhounds have learnt from experience the correct way to train the heart. The heart is a muscle, and must be trained progressively. Its rate of contraction varies greatly in different healthy men; some men at rest have a pulse rate of fifty, others of eighty per minute. There is no uniformity, but in all men there is a response to exercise. Muscular work may increase the rate to one hundred and sixty per minute, and thus it will be seen that the man with the slow pulse has the greater range. It is found that many of the best athletes have a slow pulse, and that the general effect of progressive training is to produce a slow beat of the heart during rest, and a more rapid return to this rate after strenuous exercise. A weak heart is not made stronger by the avoidance of muscular work; it should be exercised by slowly increasing the amount of work to be done.

The *Respiratory System* has exerted a peculiar fascination upon the authors of systems of physical training. Do not the lungs take in the life-giving oxygen and discharge the poisonous gas, carbon dioxide? Therefore they maintain that the lungs must be made to do their work more efficiently by special breathing exercises. The air is to be drawn through the nose by a deep expansion of the chest and to be expelled with a blowing noise through the mouth. Such breathing exercises, notwithstanding the fact that they have been approved by the Board of Education, are absurd in theory and useless or even dangerous in practice. The body does not take up more oxygen than it requires however much the lungs are ventilated, and if too much carbon dioxide be removed the subject becomes giddy and stops breathing. Another result of this exercise is that, when a class performs it, the spray of the breath containing any infectious germs, which may be present in the throats of some of the members, is spread broadcast and is inspired by others. It is no wonder that compulsory education and breathing exercises have coincided with numerous epidemics among school-children.

Healthy children do not require teaching how to breathe; they have breathed without the exercise of any thought from the time they drew their first breath. At rest they will breathe through the nose, and during hard exercise they will open their mouths, for the resistance to the passage of the air is thereby diminished. They are right; the extreme views advocated by some teachers of breathing exercises are wrong. It is not necessary to teach healthy children to breathe through the nose; they learnt this at their mothers' breasts. No infant can suckle properly and breathe through its mouth; every intelligent mother who has suckled her child knows that it breathes through its nose, and that trouble arises if the passage of the air is prevented by the pressure of the nose against the breast, or by the accumulation of mucus during a cold.

Athletes and the trainers of racehorses have learnt by experience how to train the lungs. By progressive exercise the respiratory system is stimulated in the natural manner; the muscular work of running produces more carbon dioxide and uses up more oxygen, the nervous system responds to the changes in the blood and the respiratory muscles contract more frequently and forcibly. A further advantage is that the heart is stimulated and trained at the same time.

Special gymnastic exercises have been devised with the purpose of expanding or opening out the chest. The result can often be seen in soldiers who tend to fix their chests in a partly distended condition. There is no reason for such bad exercises. The increased girth of the chest produced in this way is often only apparent, and is due in some cases to a special development of the muscles of the chest, and in others to a forcible displacement of the stomach into the chest. A big chest is no proof of a "good wind," although it is true that healthy men who have led an active life often possess

well-developed chests. The body works as a whole, and a "good wind" can be acquired only by progressive exercise, such as running. This produces those complex chemical and nervous changes which result in deeper and quicker breathing, and a more rapid contraction of the heart.

There is a further serious objection to breathing exercises. The authors of systems do not agree in their teaching; some proclaim thoracic, others abdominal breathing. This lack of agreement one would expect, for the truth is, that the types of breathing vary not only in different individuals, but even in the same individual, according to the conditions involved during rest and work. There is no exact knowledge of the muscles involved in respiration, and dogmatic teaching on the question is a sign of ignorance.

The *Muscular System* must be studied in the living, not in the dead subject. Anatomical knowledge, unbalanced by an education in physiological principles, has had a pernicious effect upon systems of physical training. A knowledge of the names of the bones and muscles is not necessary for a good trainer or instructor. The authors of systems have been misled by their knowledge of anatomy, and have designed exercises to develop each muscle; no postures, however unnatural, have been neglected in the attainment of this end. It has been pointed out already that the uniform development of the muscles is not desirable; muscles which are not constantly used in everyday life do not require excessive development, for an unnecessary drain is thereby made upon all the other systems of the body. Agility and capacity to perform movements smartly cannot be obtained by developing big muscles by special bends, or exercises with dumb-bells or heavy weights.

No man can be trained in any special manner by a course of exercises designed to develop one by one his different muscles. If he wishes to become a runner he must practice running; if he will become a good oarsman he must row; if he must perform any given work efficiently he must learn by doing it. This has been the English method; the work is done, the theory may or may not come later.

The *Nervous System* is concerned in all muscular work, and derives far more advantage from games and sport than from drills and gymnastic exercises. Games and sports are pursued for their own sake, for the pleasure and interest which they afford. It is a morbid taste, which makes a man use a so-called "exerciser" attached to the door of his bedchamber, because it has been suggested to him that by so doing he will learn how to live and how to escape disease. The suggestion may do him good, and any exercise is better than none at all.

The sportsman, be he a man or a boy, does not consider whether his sport will prolong his life; on the contrary, he ignores warnings that it will ruin his health or cost him his life. He pursues his game because he likes it; he has not become so civilised that he has lost the primitive instincts how to live as a man. He learns by experience to rely upon himself, to meet unforeseen emergencies, and trains his eye and sense of judgment.

There is always a medicinal flavour about drill and gymnastic instruction. It is a corrective. There is a sense of restraint, a suppression of the personal equation, an undue fatigue due to muscles unnaturally used, and to the conflicting nervous impulses produced in response to orders. There is no purpose in view in many of the Swedish exercises except the medicinal. This does not appeal to the English man or boy; in fact, in some schools one hour's drill is given as a punishment.

The nervous system is stimulated by games in the open air; the exposure of the skin to cold and wind produces a tonic effect which is wanting in the drill-hall or gymnasium. Immunity to the effects of changes of weather, to the dangers of chills and colds, can be obtained best by open-air exercise in all weathers. Colds are in-

fectious diseases, and are more liable to spread in closed rooms than in the open air. The dust of the floor and of the mats in a gymnasium is a source of danger which requires more recognition. Insistence upon the importance of exercise in the open air will do much to mitigate the evils of gymnastic courses, for it imposes an obstacle to the erection of gymnastic furniture.

The *Digestive System* is benefited by muscular work, for a greater appetite is produced and nutrition is improved. No special limitations in the nature and quantity of the food are necessary; likes and dislikes are in the long run the best guides of a healthy child or adult. The man who takes sufficient daily exercise runs no risk of becoming corpulent when he eats as much as he desires. One never sees a fat constable in rural districts, but in the City, on "point" duty, such officers can be found without difficulty.

It is recognised by trainers that severe exercise should not be performed directly after a heavy meal. A more active circulation of the blood is required by the abdominal organs during digestion, and this would conflict with a similar need upon the part of the muscles during severe exercise. The result would be impaired efficiency of both systems.

The *Cutaneous System* plays an important part during exercise, for the secretion of sweat and the flushing of the skin with blood lower the temperature of the body. The skin is, moreover, the largest sensory area of the body, and exercise in the open air exposes it to heat and cold. In such a manner accommodation to changes of temperature is acquired. This is often known as the "hardening process," and it possesses a sound basis.

It is an advantage to push exercise to the stage of sweating, for thereby the regulating powers of the body are trained, and the skin is cleansed in a natural manner. The labourer who lives by the sweat of his brow is much cleaner than one would expect from his meagre use of baths.

A detailed consideration of the effects of muscular exercise upon all the organs of the body would be impossible, on the grounds of want of both space and knowledge. There are, however, a few more points which must be mentioned. The living body is constantly compared to a machine, and the effects of work are considered from that point of view. It is forgotten that the body is more wonderfully and perfectly made than any machine. It possesses the power of self-adjustment and of repair; with use it grows and becomes stronger, and at the same time more economical in its working. It cleanses itself and is self-guided to supply the energy requisite for its work. It has a range of adaptation to different kinds of work, and a duration of life far greater than the capacities of any machine.

Another question to consider is the significance of fatigue, muscular soreness, and pain. These are not evils, but warnings which protect the body from damage. The natural response to such sensations is rest and sleep, time is given to the processes of restoration. On the other hand, the best method of inducing healthy sleep is muscular fatigue of moderate degree; muscular exercise cannot be taken without nervous activity, but severe mental work is often unaccompanied by muscular activity sufficient to produce those complex chemical changes which accompany healthy fatigue. One of the factors in fatigue appears to be the presence of poisonous substances, or toxins, in the tissues. By exercise the body is trained to combat the early onset of these effects, and a great power of resistance can be acquired.

It might appear from the previous remarks that games and sports are free from defects. Such is not the case. Although progression is recognised, far too much importance is attached to records. In a race the man who comes in first is considered the victor and the best man. This is a bad test. The condition of the man at the end of the contest is an important factor which is not re-

corded by the stop-watch. In some contests, such as *The Daily Telegraph* Cup for marching and shooting, this is recognised. A soldier who has marched or run himself out is not steady enough to shoot straight.

Although there are games and sports suitable for all ages and degrees of physical fitness, many men and women who live somewhat sedentary lives unwisely devote their holidays too vigorously to muscular exercises. They have not been trained sufficiently, and they may be so overstrained and fatigued that their holidays do them more harm than good. Time is required for accommodation to any great change in life, and a man who is going for a tour on his bicycle, or will row or climb during his holidays, would derive far more pleasure and benefit if he devoted some of his time beforehand to progressive training.

Diet is often a stumbling-block in the way of trainers and athletes, and, owing to the special pleadings of some writers for the daily press, fashions in diet arise. There is no standard food; what is good for one is bad for another. A healthy man is guided by his likes and dislikes, and the man is a degenerate who requires to be taught by his newspaper how, when, and what he should eat. A man in training for a severe contest should take as much simple food as he can enjoy, but he should not be dieted according to any rigid rule. The condition known as "staleness" appears to be due to a rigid insistence upon some definite diet during training. A man can learn only from experience what diet suits him best.

There is a general opinion among athletes and trainers that alcohol and tobacco are liable to do more harm than good. The use of these drugs is an acquired habit, and abuse often occurs. There is evidence that efficiency in

the performance of muscular work is diminished, and that the accommodation of the heart is impaired by their use. Too narrow a view, however, must not be taken, for it is often found that an excess of virtue is accompanied in many cases by a lack of manliness. The sudden prohibition of moderate drinking and smoking may cause so much discomfort and discontent that there is no compensation.

Much has been written concerning the danger of injury during certain games and sports. The alarm has been sounded chiefly by those who do not recognise that the bad results must be taken with the good. The result as a whole is excellent, both from a moral and a physical standpoint, and the death or injury of a few individuals is far less serious to the race than the loss of manliness. The discipline of most games and sports is so good in this country, that there is little risk of wilful injury of one competitor by another.

In conclusion, it is only fair that some credit should be given to gymnastic systems. They do good to those who will not take exercise in the form of games and sport, for they include many excellent features such as climbing, jumping, and balancing. Gymnastic exercises can be organised for large classes, and for the purpose of discipline, but they require revision. It is to be hoped that the systems might be developed in this country in two divisions, one consisting of exercises of the nature of games and sport for the sake of the healthy; and another of corrective exercises performed under medical supervision for the cure of defective development or deformities. Such a change would be in conformity with the national characteristics of this country, and with the teaching of sound therapeutics.

NOTE.—The figures for the Current Year are approximate only.

* As Diseased or Exposed to Infection

Inspection of Show Dogs.

Trouble seems to have arisen between the Kennel Club Committee and the veterinary surgeons with reference to the examination of dogs at dog shows. At a big London show last month the veterinary surgeons refused to allow a number of dogs admittance, because of the signs of some disease.

It appears now that two dogs belonging to one kennel were found to be suffering from some skin disease, and two veterinary surgeons who examined them came to the conclusion that it would not be safe to allow them to be benched.

The owner, not being satisfied, lodged a complaint at the Kennel Club, but in his complaint only mentions one dog, while the veterinary surgeons in their report mention both dogs, and say that, in their opinion, as the two dogs came from the same kennel it was not safe to admit either to be benched.

It seems extraordinary that the Kennel Club Committee, in upholding this exhibitor in his contention that the one dog was not suffering from the skin disease, fail to mention about the other dog.

If the Kennel Club Committee overrule one of their own rules, how can they expect the general body of exhibitors to abide by laws made by them.

If the Kennel Club Committee do not stand by the veterinary surgeons—and the veterinary staff at this show were all men with long experience and specialists in the diseases of dogs—what assurance can exhibitors have that dogs suffering from all sorts of diseases will not be benched at these large shows. It would simply mean that large dog shows would become a hotbed of canine diseases.

The dogs at any of these large shows, where 1,500 to 2,000 dogs are benched, are worth from £150,000 to £200,000, and numbers of these dogs would lose their lives simply because the veterinary examination had become a farce, examining "vets" not having the power to refuse a dog they suspected was diseased.

It is in the early stages of most canine diseases that infection is most probable. In distemper for instance, it is in the early stage that contagion is dangerous, and all the authorities on this disease state that the dog should be at once isolated.

This question is a most important matter for exhibitors, and for the general public at large. It is a well-known fact that a person handling a dog in the early stages of distemper can carry the disease for such a time that any dog being handled afterwards—though it may be some hours later—would in all probability contract the disease.

THE "VET'S" DEFENCE.

The veterinary surgeons in their report distinctly say that if they had permitted these two dogs to be benched they would have been guilty of gross negligence and unworthy of the confidence of the exhibitors.

If any exhibitors had lost a dog through the "vets." allowing a dog to be benched, knowing full well that he was suffering from a contagious disease they would be liable to be prosecuted, and the exhibitor could claim the value of the dog.

Further, they would, under the veterinary surgeons' rules, be liable to be struck off the rolls of the Veterinary College.

In face of all this, the Kennel Club Committee inform these veterinary surgeons that, in their opinion, the dog mentioned was not suffering from any skin disease of a suspicious character, and that the owner was justified in bringing his complaint before them.

RELWOF.

—The Evening Times.

College Crest Appeal Fund.

Dear Sir,

I herewith enclose list of subscriptions received towards the Fund. May I ask those of your readers who have promised subscriptions to forward them as soon as possible. I am informed that the L.C.C. has retained an eminent counsel for the case, and it is very desirable that our preparations for the defence of our privilege should be adequate.—Yours faithfully,

HAROLD A. WOODRUFF.

OBITUARY.

THOS. G. SHERWOOD, M.R.C.V.S., New York City, U.S.A.
Graduated, Glas : April, 1883.

Veterinarians, not only in New York City, but throughout the country, will be shocked to learn of the sudden and violent death, on July 24, of Dr. Thos. G. Sherwood, of New York, who has long been recognised by his colleagues in that city and generally as an authority on canine diseases. Dr. Sherwood was driving an automobile, accompanied by his wife, when the machine skidded and plunged over an embankment. Mrs. Sherwood sustained cuts on the hands, face and body, and suffered from shock; but was not seriously injured.—*A. V. Rev.*

WM. WORTHINGTON, M.R.C.V.S., Wigan, Lancs.

Edin : April, 1863.

Mr. Worthington died on August 8th at "The Glen," Shevington. Aged 70 years.

Personal.

Prof. W. O. WILLIAMS, of Liverpool, has been appointed Veterinary Referee to the forthcoming Dublin Horse Show.

With reference to the announcement from Capetown that, after exhaustive experiments conducted in Griqualand East, a method had been discovered of rendering cattle immune from East Coast fever, we learn that the veterinary surgeon in question is Mr. F. Chambers, son of Alderman T. Chambers, M.R.C.V.S., of Dudley. It will be remembered that he had a brilliant college career.

The decision of Dr. J. G. Rutherford, C.M.G., to forsake the Department of Agriculture, for the broader and more ambitious field of politics, will be heard with a feeling of pleasure, tinged with regret. Although the great and growing province of Alberta, which it is said will be the scene of his political activities, needs men with the weight, vision and statesmanship of J. G. Rutherford, yet Canada as a whole can ill afford to lose the services and genius of the man who has so faithfully and capably filled the position of live stock commissioner of the country during the past few years.

Countless instances could be related of his genius and

ability in righting live stock troubles that promised to blight the great pursuit. Perhaps one of the greatest tributes to his worth as a man and a servant of the agricultural interests of the country was witnessed last week when a delegation composed of the leading live stock men of the country waited upon him in a last vain effort to have him reconsider his determination to resign. The clamor which has gone up from the farmers from one end of the country to the other, and the hundreds of communications to the Minister of Agriculture asking that his resignation be not accepted, attest his worth and popularity.

What will be Canada's loss will be Alberta's gain. For few men in Canada have a broader grasp of national politics. His health was never better, and therefore it is hoped that the province to which his great gifts will in the future be devoted will enjoy and appreciate his services.—*The Ottawa Evening Journal*.

PROFESSIONAL FEES.

Sir,

Your correspondent "Rusticus" candidly admits he does not keep an infirmary, therefore the conclusion must be come to that he does not know anything about the conditions of keeping one. As a rule the most caustic critics are those who know nothing about the subject they criticise. "Rusticus" insinuates my letter was prompted by spite and stupidity, but does this not again show his ignorance, especially as Mr. Pope neither mentioned the name nor address of the "successful firm."

It is not a question how much an animal costs to keep, but how much should a veterinary surgeon charge for his skill and trouble that he might live reasonably and allow his confrères a chance in the struggle for existence. The motto of the older Englishman was, and that of the modern trade unionist is—"Live and let live." This motto has been well illustrated during the past week, where the British workman has shown "Unity is strength."

Is it not more remunerative to visit a cat or a dog at 2/6 (many charge 5/- and upwards) than keep and treat one with a certain amount of trouble and perhaps the risk of damage to one's reputation at 4/6 per week? Again, is it not more economical and profitable to castrate one colt at 10/6 than perform on two for 5/-, or even 3/6 each? The avaricious man will do it at any price so as to keep his neighbour out. Such a one even sometimes takes in non-professional pupils and teaches them castration, etc., for a fee, and then turns them adrift to compete with neighbouring practitioners. I hope "Rusticus" is not like this. However, unqualified men and quack medicine vendors often charge more than duly qualified and registered practitioners.

The probable explanation of the fee of 10/6 as charged by Mr. Pope is, this gentleman gives more time and attention to his patients and spends more on space, soap, and water than his confrères who charge 4/6.—Yours, etc.,

"VIS UNITA FORTIOR."

REMEDIES FOR FLIES.

Sir,

Oil of sassafras possesses marked insecticidal properties. It contains on an average 80 per cent. of Safrol, with small amounts of Pinene, Phellandrene, together about 10 per cent.; Dextrocampa 7 per cent., Eugenol about 0.5 per cent. and Cadinene.

Camphor oil is the most common adulterant of Sassafras oil, as it contains all the constituents of the latter.

An unusual case of poisoning by Oil of Sassafras is recorded in *The British Medical Journal*, February 25, 1911. The oil was applied rather copiously to the back of a healthy Scottish terrier dog which had become infected with pediculi, and the application was repeated several times during about a week. The result on the dog was to make him ill, and he refused his food and became very weak.

A veterinarian who was called in told the owner that he thought the dog was poisoned and that he had seen two similar cases to this one. In all three cases absorption had taken place through the skin and not by the dog licking himself.

The dog eventually died about a week after the last application of the oil. Post-mortem it was found that the liver and kidneys were congested, the former being considerably enlarged.

Another useful insecticide is *Ol. Betulae alb.* (B.P.C.) which is non-sticky and easily incorporated with lard.

To clear stables, cowsheds, and other places of flies, the following solution should be placed in shallow trays in various parts of the building:—Solution of Formaldehyde 6, beer 13, and simple syrup 1. The latter remedy was given in *The Pharmaceutical Journal* recently.—Yours, etc.,

W. J. YOUNG, F.R.C.V.S., D.V.S.M. (VICT.)

Sheffield, Aug. 14.

SHEEP AND WATER SUPPLY.

Sir,

I should like to call the attention of some of the readers of *The Veterinary Record*, especially veterinary students and newly qualified men, to the discussion on Prof. Craig's excellent paper—"Some notes on the passage of fluids through the stomachs of ruminants," delivered before the Veterinary Medical Association of Ireland. The report of this meeting was in your last week's issue, Aug. 12.

In the discussion, Mr. Howard said "it is a common thing to find sheep in various parts of Ireland that have never been known to have a drink of water, and they do well and are perfectly healthy."

Mr. A. Watson said that, "he thought he was right in saying that sheep as a matter of fact did not drink water. It was a symptom that they were unwell when they took to water."

I consider the above expressions erroneous and misleading, more so because they have been used by two well known veterinary surgeons. I really think that unless we have fair knowledge of the natural habits of the animals we treat, we are of very little use to our clients. On the other hand, if we have a real knowledge of the natural mode of living of our patients, this knowledge in time "converts itself into practical power." I hope Mr. Wallis Hoare in his book on Veterinary Medicine will deal more fully with sheep than the books which we have already seen on veterinary medicine.

May I tell Messrs. Howard and Watson that there are hundreds of sheep in this neighbourhood suffering through the lack of water supply on the pastures. One of the most important questions of the sheep farmer is about the water supply on the farm, especially on a summer like this. At the time of writing this short letter, I see several thirsty ewes imbibing at a little stream which runs through one of our fields. During a dry summer like this, water is as essential to sheep as it is to cattle, although they don't get access to it as often as cattle.

If any reader doubts the accuracy of the above statements, I should like him to drive a flock of sheep along the road near a running brook, and notice whether they will drink of the water. As sheep are very timid little animals, the dog ought to be kept a good distance from them.

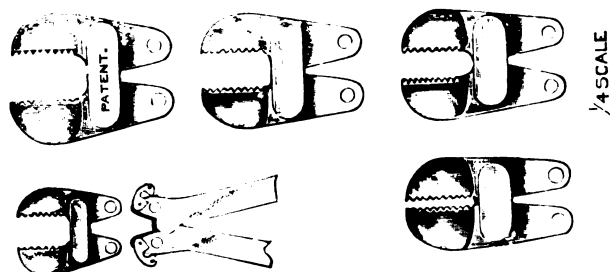

The stomach of the sheep contains as much fluid contents when opened, as the stomach of the ox, in proportion to the size of the animals. Again, the sheep perspires more than the ox (according to some physiologists the ox does not perspire, this theory is absurd, which I hope you will all agree). Therefore if the same quantity of fluids (in ratio to the size of each animal) is found in the stomach of the sheep and the ox, whilst the sheep perspires more than the ox, the sheep according to every reasoning, must drink as much, if not more water than the ox.

I hope this short letter by one who has been managing a large flock of sheep for twenty years, will stimulate some of our members to bring an interesting paper on sheep before our Veterinary Associations, the same as Professor Craig did.—Yours faithfully,

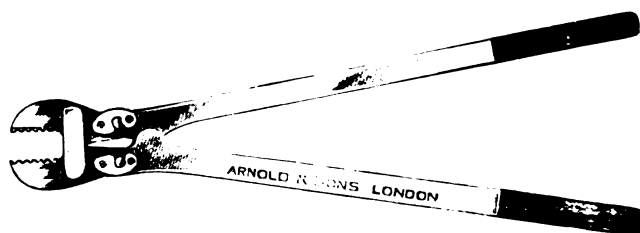

"KERRY HILL."

Borough of Reigate

TUBERCULOSIS. INSPECTION OF COWS.

THE Council of the Borough of Reigate invites applications for the post of Veterinary Inspector of Cows. The person appointed, who must be a qualified veterinary surgeon, will be required to examine all cows in registered cowsheds in the Borough at least four times during the year, and report on the same. At the end of 1910 there were 9 registered cowkeepers, and 177 cows. Salary, £20 per annum.

Applications, sealed and endorsed "Inspector of Cows," are to be sent to me at the Municipal Buildings, Reigate, on or before Saturday, the 9th day of September, 1911.

By Order, ALFRED SMITH, Town Clerk.

Dated this 24th day of August 1911.

Wanted

EXPERIENCED qualified locum, from the 7th to about the 24th September. Apply, with particulars to F. G. Edwards, F.R.C.V.S., Newgate Street, Chester.

As Assistant or Branch Manager

EDINBURGH.

Veterinary Surgeons have for long keenly felt the want of something which could be used with good results as a Uterine Antiseptic and which at the same time could be quickly and easily administered. After many trials, and with the kind co-operation of some able Veterinary Surgeons of great experience in parturition cases, we have succeeded in producing

a Pessary made with a non-oily base which does its work efficiently and at the same time is non-irritant—in fact, soothing in its effect. They are of great use in parturition in cows or mares; and if administered immediately after parturition they will keep the Uterus clean and healthy, and prevent the after-birth becoming foul.

Veterinary Surgeons in various parts have highly recommended them, and there is an increasing demand for both kinds.

Customers are requested when ordering to state which kind they prefer.

A RECENT UNSOLICITED TESTIMONIAL.

AINSWORTH WILSON, ESQ., F.R.C.V.S.,
writes:—

"I have used the Saloform Pessaries supplied by Messrs. Harkness, Beaumont & Co., of Edinburgh, with good results in various diseases of the genital organs, both in mares and cows, more especially after parturition. They are particularly useful in retention of the afterbirth, with septic complications. It is often impossible to attend more than once a day to irrigate the uterus; in such cases it is good practice to leave one or two of the "extra strong" pessaries *in situ*. I have found them an excellent substitute for Iodoform and other well known non-irritating antiseptics. I feel justified in recommending them to the profession.

Witham, Essex.

THE VETERINARY RECORD

A Weekly Journal for the Profession.

EDITED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1207.

AUGUST 26, 1911.

VOL. XXIV.

DISEASES OF ANIMALS IN GREAT BRITAIN, 1910.

The Board of Agriculture has issued the Annual Report of the work done in 1910, and although some of it is rather stale there is a great deal both interesting and useful.

"No outbreaks of Cattle-plague reported since 1877.
No outbreaks of Pleuro-pneumonia reported since 1898.

No outbreaks of Rabies reported since 1902."

That alone justifies a Veterinary Department. Other diseases we have with us still.

Foot-and-Mouth Disease appeared last year in Yorkshire in one of those unaccountable outbreaks which cannot be traced, and which are liable to reach us whenever the disease is very prevalent in Western Europe. If one looks back to the time when the disease prevailed in this country some idea may be formed of the danger these small invasions possess and the enormous loss which is prevented by the energetic action of the Board in stamping them out with rigour and dispatch.

In 1883 no less than 461,145 animals were attacked with Foot-and-mouth disease—cattle, sheep, and pigs. By 1887 the country was cleared.

In 1892 disease appeared and lasted for three years affecting 5065 animals. In 1900 Foot-and-mouth was again reported, and was not got rid of till 1903.

In 1908 a small outbreak occurred, and in 1910 a still smaller. It is very satisfactory to find that such a disease, which we cannot entirely keep out of the country, should be so rapidly stamped-out.

Swine Fever is the *bête noir* of the Board. In 1910 there were 1598 outbreaks—about the same number as the average yearly returns for the previous nine years. The Chief Veterinary Officer discusses the disease very briefly, mainly in reference to the difficulties of diagnosis, but he is silent on some subjects only because the Departmental Committee had not yet reported. We may therefore expect in next annual report some larger reference to the difficulties which the Board has failed to overcome.

The Assistant Secretary in his report is not very optimistic. He says: "It must be admitted, however, that the position generally leaves much to be desired, and it is not easy to see how any substantial improvement is to be brought about in the near future."

Anthrax. The outbreaks of this disease in 1910 reached 1496, showing a gradual increase since 1906, with the usual 1.1 per head per outbreak. The present report is the last which will deal with

the disease under the Order of 1899. The operation of the New Order will afford some interesting comment in next year's report. The Assistant Secretary says: "It is believed that the new Order will be of service in securing the collection of more trustworthy statistics to form a basis upon which to build up any other measures which further experience may indicate as likely to reduce the risk of infection."

Sheep-scab. The number of outbreaks in 1910 was 556, that is 129 fewer than in 1909. Wales comes first with 237 outbreaks, then England with 204, and Scotland with 115. It seems the regulations are doing good. An investigation into the epizootiology of the disease which was outlined in the report for 1909 is being carried out. It would be inadvisable, however, to report further at present, as the enquiry is not completed. We believe the enquiry has elucidated some important questions concerning the cause and spread of sheep-scab.

Glanders.—This disease is certainly yielding to the action of the 1907 Order, which came into operation on Jan. 1, 1908. The figures are as follows:

	Outbreaks.	Horses attacked.
1908	789	2433
1909	533	1753
1910	351	1014

The number of horses attacked seems large, but it must be remembered that a large proportion of these were discovered by mallein, and that few of them were infective when slaughtered. The trustworthiness of mallein as a diagnostic agent is shown by the Chief Veterinary Officer's report, which says "In six reactors no lesions could be found at the post-mortem examination. In only one case was no reaction obtained to mallein, although glanders lesions were found on post-mortem examination. Under the provisions of Article 9 of the Order, the nature of lesions was disputed by the owner's veterinary surgeon in four reactors to the test, and the cases were submitted to the veterinary officers of the Board for decision; glanders was not confirmed in any of these cases.

Some pages are devoted to the work done in the laboratory, which we shall leave for fuller quotation than can be given on this page.

Exportation of horses. Since the 1st of October last the Board has taken over the regulations governing the shipment of horses to the Continent. It appears that this traffic is now carried on under very improved conditions, and that even the inland transit of horses has improved owing to the action of the inspectors and of the railway companies.

Altogether the report may be accepted as satisfactory. If the Board has not always been successful in its efforts to control disease it has done much, and its officials face their work with knowledge and with a determination to master their difficulties.

FRACTURE OF TIBIA IN SIXTEEN YEAR OLD HORSE—RECOVERY.

Subject. Three-quarter bred stallion, sixteen years old. A well known Colonial sire, his progeny having won numerous prizes.

History. Found in the stable with a broken leg, probably caused by getting his leg under a swinging bale. Seen by me a few minutes afterwards, and fracture of tibia diagnosed, in lower third of bone without any displacement.

I advised immediate destruction, but the owner was so keen on having a try to patch him up for one more season, that—much against my better judgment—I resolved to make an attempt.

Treatment. Being situated in a small up country town, this was somewhat "rough and ready" but we managed to improvise quite a serviceable set of slings out of wool bales padded with sheep skins. The animal was placed in these, and the injured leg bandaged from the stifle to the hock with stout canvas bandages, over which ordinary melted pitch was smeared, a few inches at a time, (the limb was of course first enveloped with a good layer of cotton wool), this bandage was put on several layers thick, and set as hard as a board. The limb was bandaged with an ordinary bandage from the hock to the foot, and the other legs were also bandaged. This pitch bandage kept in place beautifully for six weeks, when it was removed. The animal was kept in the slings for eight weeks, and he was a very good subject taking to them at once and never struggling. A contrivance which I found of great service was a padded pole placed just under the buttocks; on this the horse would literally "sit" for hours at a time. Beyond two subcutaneous injections of morphia on the first two days, and occasional doses of Mag-sulph. in the drinking water, I did not trouble about medicinal treatment. A few sores on the belly and around the sheath made their appearance, but these soon yielded to ordinary antiseptic treatment.

After four weeks in the slings the horse began to put a little weight on the leg, and when the bandage was removed after a period of six weeks, he was allowed to stand on it for an increasing time each day. When he was removed altogether from the slings (after eight weeks) he was run in a small paddock, and here he used to lie down and sleep for hours at a time. At first he had to be helped up, but gradually he managed this for himself, and eventually was walked out to the farm, a distance of about nine miles. Here his recovery was uninterrupted and when I saw him again about four months afterwards he could trot, canter, and gallop with only a slight limp. He was used at the stud that season and covered twenty-five mares.

He died next year (during his owner's absence) from septic poisoning, occasioned by a wound which had not been attended to on the other leg, and I was fortunate to obtain both Tibias. The actual shortening was $2\frac{1}{2}$ inches, and it was surprising to see how little this affected the animal's gait during life.

I am sending you these notes to demonstrate the fact that it is worth while making an effort to save valuable stud animals in cases of simple fracture, when no complications are present. I know the animal's disposition has a lot to do with it, as when they "fight against the slings" treatment is hopeless from the start, but I cannot help thinking that we are sometimes a little too ready to advise destruction.

A. GOODALL, M.R.C.V.S., Govt. Vet. Sur.
Kokstad, E. Griqualand.

A PECULIAR CASE OF STRANGLES.

As a result of the numerous articles which have appeared latterly in connection with streptococcic infections, a positive stimulus has been provided to many of the subscribers to our interesting and increasingly scientific journals to report matters of bacteriological importance, a result which should be looked upon with satisfaction by the profession generally, but more especially by the Colonial veterinarian, to whose lot falls a bewildering and chaotic fundament of bacterial diseases.

The accompanying photograph is of a three year old black gelding, and illustrates the subject of the case I wish to record. The following are the facts of the case. I was asked a few months ago by my *confrère*, C. V. S. Goodall to look at this gelding. He had a strangles abscess deeply situated in the gluteal muscles, which had been opened, and drainage and irrigation provided for. He had at the same time an abscess in the off knee joint which had already begun to point. A guarded prognosis was the result, but grave doubts existed in our minds as to the probability of its future being rosy. This suppurating condition was relieved somewhat by my abscess knife, and directions given as to treatment, which comprised Lugol's Solution locally and Iodide of Potassium generally. He was, however, allowed to wander about on the veldt, and housed at night. The wounds receiving daily dressings.

A microscopical examination of the pus revealed streptococcic chains.

Last week my attention was again drawn to this case as he was not progressing satisfactorily. Suppurative arthritis with ankylosis with extensive osteophytic deposits had resulted, whilst a partial break down had occurred in the near limb as a result of saving the other. We advised destruction. The internal organs and abdominal parietes seemed, on a cursory examination made under a blazing sun, free from streptococcic foci. I accordingly removed the affected joint and on a careful dissection being carried out, numerous pus centres existed in the interior of the joint, with gelatinous infiltrations into the softer tissues, and osteophytic deposits accompanied by ankylosis of the smaller bones.

SOME QUERIES WITH REFERENCE TO CERTAIN GASTRIC AFFECTIONS OF RUMINANTS.

By E. WALLIS HOARE, F.R.C.V.S.

Being engaged at present in the preparation of a section on "Diseases of the Digestive Organs in the Ox," I should feel greatly obliged if practitioners having experience in this subject would give me some information on the following points:—

(1). Does impaction of the Omasum occur as a disease *per se*?

Most text books describe this disease, giving symptoms, diagnosis and treatment.

The late Prof. Williams, however, (Principles and Practice of Veterinary Medicine) doubted its existence as an affection *per se*, and pointed out that it was generally associated with inflammation of the abomasum, and that the impacted condition of the omasum was the result of disease of the other divisions of the stomach. Careful post mortem examinations should decide the question.

So far as my experience goes, I have always found inflammation of the abomasum associated with an apparent impaction of the omasum. I say apparent, because it is difficult to decide what is the normal condition of the omasum; I have seen this organ with the contents varying from a soft condition to a hard and dry one, in animals that did not suffer from any gastric affection.

Again, when one considers the large doses of irritant purgatives that are generally administered to cattle prior to professional attendance being obtained, it is not surprising to find inflammation of the abomasum present. If impaction of the omasum really occurs to the extent described by some writers, the organ being hard and tense and the contents hard and dry, can anyone explain how medicinal agents can overcome the condition?

Judging by the anatomy of the organ it is difficult to see how the heroic doses of Epsom Salt, Aloes, Linseed Oil, etc., can clear out the hard contents, and have we any evidence that these agents during their passage through the viscus exert any action thereon?

We draw deductions from the condition of the organ after death, but in the cases that recover we cannot definitely state what actual derangement was present. No doubt "Impaction of the 'Book' Stomach" is a very favourite diagnosis, and heroic measures are often adopted in order to overcome the condition. It is not uncommon to find that after large amounts of raw linseed oil are administered to cattle, suffering from a paralytic condition of the stomach, no purgative effects are produced.

And the quantities of this agent that can be given to cattle under these circumstances is surprising; one is often anxious to know where it goes to. Farmers often remark, "The oil is passing through the animal, but she is not purging." It would be interesting to ascertain whether large doses of linseed oil do enter between the leaves of the omasum, and cause softening of its contents.

In connection with this subject; one would also like to enquire—what is *Murrain*? We hear of "Dry Murrain" and "Red Murrain," and the terms seem to be applied to every obscure disease of the stomach of the ruminant. So far as I can judge the terms should be expunged from the nomenclature of diseases; they resemble Blain, Gloss-Anthrax, and other indefinite words which are purely mythological, and are simply a cloak for ignorance.

If there is such a disease as "Impaction of the Omasum," surely it can be designated as such; if, on the other hand, it is a condition resulting from inflammation of the abomasum then it should not be described as a distinct affection. If the matter cannot be definitely decided, then we may as well confess our ignorance, but we should avoid using a term such as Murrain which is without meaning, and is in the same category as that favourite term, "Worm in the tail." Both possess a mystic significance for farmers and cover a multitude of diseases.

(2). The next point on which I desire information is with reference to the etiology of *gastritis* in cattle.

Inflammation of the abomasum is a very common lesion at post mortem examinations, yet can we account for its presence? No doubt we can glibly enough inform the stock owner that it is due to coarse indigestible grass, etc. But how much of this coarse ingesta enters the abomasum?

In William's Veterinary Medicine, the ingestion of large amounts of rye grass is recognised as an etiological factor, but we meet with a large number of cases in which this factor was not present.

Again, it is a well-known fact, that gastritis in cattle is not always accompanied by nervous excitement or delirium; the leading symptoms being, loss of appetite, and of rumination, obstinate constipation, and the presence of a grunt. But these symptoms are common to a variety of gastric disorders, and are also present when a foreign body causes obstruction to the opening of the oesophageal canal into the omasum.

(3) In a case of impaction of the rumen that is treated successfully by the administration of full doses of purgatives, how are the contents of the rumen disposed of?

Some may say the answer is obvious, viz., rumination goes on in the usual manner. But in an impacted rumen such as we observe at a post-mortem of a case of this affection, one naturally wishes to know how the purgative acts in the cases that recover.

No doubt the impaction is not so severe in the latter instance, still, if the medicinal agent administered enters the rumen and reticulum first, as experiments lead us to believe, it is not easy to explain how beneficial effects are produced.

(4) What is the diseased condition on which "spewing of the cud" depends?

I have searched all the text books and failed to find even the slightest reference to this affection. The cow apparently feeds well, but when rumination is proceeding, portions of food are ejected from the mouth, with the result that a considerable heap of ingesta is found in front of the animal. This ejection

tion of food is not continuous during rumination, but the animal suffers considerably in condition as the result of the loss of nutriment sustained.

I have only met with two cases of this affection, and from enquiries it does not appear to be of frequent occurrence. I should be very pleased to obtain further knowledge of the subject.

In conclusion, I may remark that the thanks of all clinicians are due to Prof. Craig for the very instructive experiments he has carried out with a view to elucidate some facts in connection with the passage of fluids in the alimentary canal of the ruminant.

One practical deduction would seem to be that medicinal agents should be given to this species freely diluted, and for a long time I have carried this out in practice with good results.

It would be interesting to ascertain how medicines in the solid form are disposed of in the stomach of the ruminant, as it is now suggested that drugs enclosed in capsules can be administered to sheep and will exert the desired effect in cases of parasitic gastritis; tablets are also advertised for a similar purpose.

ABSTRACTS FROM FOREIGN JOURNALS.

ERRONEOUS INDICATIONS FROM TUBERCULIN.

That erroneous indications may be obtained after the use of tuberculin is undoubted, and they may be classed as real and apparent. Among the real, are the failures to react which occur in animals which do not possess sufficient anticorpin to dissociate the bacillar albumen. Those which occur when lesions are very extensive; in cases of secondary infection, and old or cured lesions.

The apparent ones cannot fairly be imputed to the disease or the tuberculin and are;

1. Tuberculin weak, too small dose, or altered.
2. Faulty syringe, or injection into muscle tissue.
3. Old tuberculin.
4. Dry tuberculin, if mixed without addition of carbolic acid, deteriorates in less than 24 hours.
5. Defective or untested thermometers.
6. Low reading due to slackness of the anal sphincter.
7. Some animals react before the twelfth hour, the reaction is transient and may be overlooked.
8. Interested persons will misread the thermometer.
9. Omission to observe other symptoms beside temperature.
10. Overtired animals failed to react.
11. Animals in heat do not give a reliable reading.
12. The body heat is affected by the quality of the drinking water, mouldy forage and similar conditions.
13. Failure to react may be brought about by dosing with febrifuges, or administration of very cold water by mouth or rectum.
14. Cold and draughty sheds will diminish the reaction.—*Tijd. v. Veeart.*

TUBERCULIN ERRORS.

A strong reaction has set in with regard to the views on the infallibility of tuberculin when injected, and the newer ocular and dermal methods are more favoured, but it is premature to cast off tuberculin on account of various errors which arise on account of the idiosyncrasy or tolerance of some animals, and probably subcutaneous injection is quite as reliable as the now more favoured methods.—*Bull. Soc. Sc. Vet.*

TUMOUR ON THE HEART OF A COW CAUSING PARALYSIS.

Foss was called to a cow which the day before, on returning from pasture, suddenly staggered while eating, fell and could not rise. She lay thus for five days, when, having no hope of cure, and on account of the poverty of the owners, he advised its being carted to the slaughterhouse.

Temperature, appetite, and digestion had remained normal. Sometimes the cow became worse; it lay on its side, groaned, moved its feet and threw its head back. Ice to the head improved matters, sometimes it tried to rise, but the front legs were powerless. Unfortunately examination of the heart could not be properly carried out owing to the recumbent posture, but one could feel its weak beats and the number of pulsations was normal. Treatment with several drugs, including strychnine hypodermically, was of no avail.

Post-mortem examination revealed a tumour upon the edge of the atrium and left ventricle, it was oval, 10 cm. long, 6 to 7 cm. wide; the capsule of the tumour was fibrous, 2 to 3 mm. thick; section along the ventricle showed that the tumour continued downwards and surrounded the papillar muscle changing it to a firm cheesy mass, owing to this alteration the muscle lost its function. The mass was partly calcified. At the lower part of the tumour was some thick creamy pus. The whole capsule of the tumour was packed with a firm caseous mass of the colour of cream and the consistency of mortar.

Possibly a particle of the chalk had escaped, and circulated to the brain, causing a thrombus accountable for the paralysis. All the other organs and vessels were normal. What was the origin of the tumour? Was it tubercular? Although bacteriological examination was negative.

(From the Russian author's original Esperanto).
F. E. P.

PAPILLARY EPITHELIOMA OF THE BLADDER IN A PIG.

Schultze, of Storkow, records the following unusual post-mortem observation upon a pig. The animal, a well-bred one of about six months old, had died suddenly; and the history was that it had always fed well and appeared healthy, except that of late it had urinated frequently, and that sometimes the urine had been red in colour. No importance had been attached to this, on account of the good general condition of the animal.

Externally, the carcase showed nothing abnormal. Upon section, the organs of the thoracic and abdominal cavities showed no morbid lesions, except that they appeared very anæmic; which, in view of the good condition of the animal, was surprising. Special attention was given to the urinary apparatus, on account of the history.

The kidneys and ureters were normal. The bladder, on the other hand, was much enlarged and tensely filled. When it was manipulated a small quantity of blood-coloured urine flowed from the urethra; and a moderate amount of similar urine escaped when the bladder was incised. A large blood-coagulum also escaped from the incised bladder; and the organ, in addition, contained two soft growths the size of the fist situated upon its base.

After washing away the blood coagula still covering the vesical mucous membrane, it appeared that the two growths arose in common from a portion of the base of the bladder rather larger than a five-mark piece. They were in part blackish-brown and in part pink in colour superficially; and had a shredded tufted structure and a soft juicy consistence. The outermost tufts had a macerated appearance. Both growths were but loosely fixed upon the tissues underlying them and could easily be detached from it; when this was done, their places of origin also showed a tufted appearance. The great richness in blood of the growths was noteworthy. One growth was found to show a cavity about the size of a pfennig in its substance; and this was filled with coagulated blood and presented shredded, blood-saturated edges. The vesical mucous membrane showed no other lesions; but the wall of the bladder was greatly thickened, which the author attributes to muscular hypertrophy from exertion.

Microscopically, the tufted growths showed an epithelial structure, with a rich supply of blood vessels. The neoplasm could therefore be indubitably classed as a papillary epithelioma of the bladder. Death had occurred from hæmorrhage into the bladder in consequence of the rupture of one of the larger vessels of the neoplasm.—(*Berliner Tier. Woch.*)

W. R. C.

[The age of the subject is a noteworthy feature of this case.—TRANSL.]

TRANSVAAL VETERINARY MEDICAL ASSOCIATION.

The seventh annual meeting was held at Johannesburg on July 8th. The following officers were elected for the ensuing year:—

President.—Mr. C. E. GRAY, P.V.S.,
Box 434, Pretoria.
Vice-President.—Mr. J. G. BUSH, G.V.S.,
Box 83, Krugersdorp.
Treasurer.—Mr. J. M. CHRISTY, Assist. P.V.S.,
Box 434, Pretoria.
Hon. Sec.—Mr. P. CONACHER, G.V.S.,
Box 877, Johannesburg.
J. G. BUSH, Hon. Sec.
Box 83, Krugersdorp.

MIDLAND COUNTIES VETERINARY MEDICAL ASSOCIATION.

(Concluded from p. 127.)

"THE EPIZOOTIOLOGY OF ANTHRAX."

DISCUSSION.

Mr. GOLD said:—In the first place he would like to say how very pleased he was to the present when Mr. Stockman read his paper, which could not fail to interest anyone who was at all interested in his profession. He had very little to comment upon so far as the paper itself was concerned, and he trusted Mr. Stockman would not think he was diverging too far from the subject if he touched upon some things a little foreign to it. In connection with the diagnosis of anthrax, he thought that with the facilities they had at their command, in the vast majority of cases if they were called in in reasonable time there should not be very much difficulty in diagnosing whether it was a case of anthrax or not. There was, however, one thing he took exception to, and that was the wording of the Order of the Board of Agriculture, because veterinary inspectors were looked upon as though they could go up to a dead animal, take with them a microscope at all times of the day and say at once definitely whether it was anthrax or not. Personally, he did not think any veterinary inspector would attempt to put himself in that position. He knew the word used in the Order was "suspected," but in some counties every dead animal was suspected that had not been seen by a veterinary surgeon, whilst in other counties that was not the case. Only a fortnight ago the police in a certain district thought there was no reason to serve notices till the veterinary inspector had been down to certify that it was anthrax. In the next county when a case was reported the police at once served notices on the owner of the animal that it was a suspected case. He should like to know which way of carrying out the Order was the correct one. As to the question of whether recovery took place, he thought there was no doubt whatever about it in the case of pigs, but he would like to know whether Mr. Stockman had ever seen cattle and sheep recover from anthrax where he was perfectly certain by a microscopical examination that the animals were suffering from the disease. He knew it was very difficult to demonstrate the bacillus of anthrax in the blood of live animals such as the horse, which suffered for hours and hours before he died, but after death one was able to find some of the bacilli, though it was a difficult matter to find them in blood taken from the extremities. In some of those cases he had been able to make cultures, and in a few days satisfy people that it was a typical case of anthrax. He mentioned that fact, because they were often asked to decide on the spot whether it was anthrax or not. If there was any fear of mistaking it for blackleg, the microscope could be brought to their aid. Mr. Stockman said he had seen the bacillus of black-quarter in the blood, and it would be interesting to know at what period in black-quarter prior to death was he able to demonstrate the organism of black-quarter in the blood itself. He (Mr. Gold) had never been able to demonstrate it from the blood stream while the animal was alive. Mr. Stockman said it might be mistaken for malignant œdema, and he (Mr. Gold) thought it was so mistaken. He would therefore like to know whether Mr. Stockman, in the course of his wide experience, had come across many cases of malignant œdema in the cow. Mention had been made by the essayist of what was called the M'Fadyean reaction. He (Mr. Gold) had never had the chance of asking Sir John M'Fadyean, but he found that they got this peculiar reaction in fresh films of the blood, and even for

some considerable time after the animal had been dead; but there was no reaction when taken from cultures; and he would like to ask whether Mr. Stockman had noticed that fact.

Mr. Gold proceeded to criticise the Order of the Board of Agriculture in some of its details, especially commenting upon the different interpretation put upon it by the police in different counties. He cited the case of a farmer whose whole shed was shut up, and as the man was milking fifty cows it was a very great inconvenience and even hardship to him, without being of any practical value. He thought if a small area on each side of the affected beast was isolated it was quite sufficient, care of course being taken that none of the other animals came into contact with the spot that was isolated. With regard to the burial of anthrax cases, they were asked to plug up the external orifices, and he thought the best thing to do in the case of the nose and mouth was to put the whole head in a bag. Incidentally, he complained that the authorities sometimes permitted delay in the disposal of the carcass. In his opinion burial or cremation should take place as soon as possible. On one occasion the carcass was placed ready for burning, but because the Chief Constable had ordered cremation should be between the hours of six in the morning and six at night it had to wait exposed before a match was applied. He thought that was red-tapeism, and with the possibility of rats or even dogs getting at the carcass there was a grave danger of the disease spreading in consequence of the delay. With regard to the notification of anthrax, they were generally expected to send a portion of the blood to the county analyst as well as to the Board of Agriculture. Veterinary inspectors recognised the need of being responsible to one particular body, but they would like to know which it was. This was the first time the Board of Agriculture had taken over directly the last word in connection with anthrax, and he sincerely hoped there would be no friction between the local authorities and the Board or between the local inspectors and the Board inspectors. They all knew what had happened in connection with swine fever, and he hoped different tactics would be employed by the Board with regard to anthrax. If a man was not fit to be a veterinary inspector do not hesitate to say so. It was not conducive to the welfare of any local practitioner to find that when a pig died his voice was ignored, and some gentleman 20 or 30 miles away was brought in and perhaps he could not say himself. When a stranger was brought into a practitioner's district, the latter's client thought a slight was intended, and wondered what it meant. Now that the Board of Agriculture had taken anthrax up in the way they had he hoped there would be no cause for complaint amongst practitioners, as there had been in the case of the swine fever regulations.

Mr. R. OVER, quoting from part of the paper, said he had always understood that if one found "enlargement of the spleen with a fluid tar-like appearance of the pulp" one could make up one's mind that it was anthrax. He had examined many cases that had the outward appearance of anthrax, but he could not find the bacillus under the microscope. One case which he first suspected to be anthrax turned out to be abdominal tuberculosis, the cow being in a remarkably good condition, but complicated with heart trouble. Another case proved to be yew poisoning, another was poisoned by deadly nightshade, and yet another sudden death was due to lead poisoning. In the lead poisoning case there was nothing to point to lead as the cause of the trouble at first, and an examination of the blood revealed something unusual. He sent it with a doubtful report to the bacteriologist, who reported that it was anthrax. He (Mr. Over) was afterwards able to prove that it was not anthrax at all, but lead poisoning, Prof. M'Fadyean confirming his belief that it

was not anthrax. That went to prove that one did not always get a satisfactory report from the county bacteriologist, and also that the diagnosis of anthrax was not by any means a simple matter. The Order relating to the time of burning carcasses did not exist in his district now, although he believed it did at one time.

Mr. MARTIN considered the paper a thoroughly practical one in every way, and it would certainly prove very helpful to him in many respects. He was an inspector of the Shropshire County Council, and when he saw a case which he suspected to be anthrax he sent it immediately to the Board, but if he did not suspect anthrax he filled up a different form and sent it to the Chief Veterinary Inspector.

Mr. BROOKE said he would like to know whether it was possible to get acute colic in cases of anthrax without gland or throat symptoms. He remembered reading in *The Record* about 12 months ago that anthrax in the horse was much more frequent than was commonly suspected. If Mr. Stockman could give them any particulars about anthrax in horses it might help some of them in their practice. In mentioning counties where the disease was prevalent he would have thought Yorkshire would be included, because hides and fleeces were largely imported into that county. Mr. Stockman said that in the case of human beings it was nearly always directly inoculated through the medium of a wound. Could not the fly be a carrier of the disease? They all knew how flies swarmed round a carcass, especially in the warm weather. With regard to treatment he thought the serum treatment in animals that were highly immunised would be the safer mode, especially it could be developed. He quite agreed that foreign foodstuffs were a common source of infection.

Mr. DEVINE said that Mr. Stockman, in speaking of the diagnosis of anthrax, placed some value on the taking of the temperature of cows in byres. He (Mr. Devine) used to do that, but he had come to the conclusion that it was not of any great value, because even where there was no disease at all there were always some cattle in a byre of any size that were of high temperature. The temperature might be high from a totally different cause, and it was no evidence whatever that there was anthrax. He had not seen many cases of anthrax in horses, but in such as he had seen he had found the bacillus in the blood itself. He had made cultures, and he had also stained the bacillus, when he had always got the reaction referred to by Prof. M'Fadyean. He had tried various colours, and agreed that Methylene blue was the stain with the best diagnostic value. Anthrax had been so well studied in recent years that most of them were now pretty well up in the subject, except perhaps as to the origin of the outbreak. It was quite feasible that it came from abroad in foodstuffs, and it was possible that it was sometimes contained in bone manures, especially as those bone manures were often got in the district where the animals had died from all sorts of diseases. Whatever protective measures they employed they had no guarantee that they had accomplished any real good. If they got an outbreak year after year and then used antitoxin successfully, they were no doubt satisfied that they had done some good, but in the ordinary way they never knew how far their precautions had succeeded.

Mr. MARTIN recalled the fact that Prof. McCall used to tell them that anthrax was generally seen at the end of a consignment of cake, as though the spores had fallen to the bottom, and he (Mr. Martin) was bound to say that that had been his experience also.

The PRESIDENT, in closing the discussion, said he was very pleased at the discussion, because it showed that they had all appreciated Mr. Stockman's kindness in coming to them a second time. It was a paper which he

knew many of them were most anxious to hear, and he was sure they had all gained something by it. With reference to the question of reporting sudden deaths to the police, farmers had got into such a state that when an animal was found dead they rushed off immediately and told the nearest policeman. The police took the case in hand and unless the veterinary surgeon was a duly authorised inspector he had to get out altogether. He could do nothing in the case and got no redress whatever. He mentioned a case of police interference where they even stopped the man from selling his milk, and as it turned out they had overstepped their powers, and when the man was advised to send in a bill for eight guineas the police paid it without a murmur. He agreed with Mr. Gold as to the importance of the carcass being buried or burnt at once, and said he knew of a case where the carcass was left for four or five days in the hot weather because there happened to be a delay in getting the inspector's certificate.

REPLY.

Mr. STOCKMAN, in reply, said it had given him very great pleasure to attend the Midland Association a second time and listen to this criticism of his paper, and he would like to thank the Association for the kind way in which his paper had been received. Dealing first with the remarks of Mr. Gold he was bound to say that whatever else Mr. Gold had been he had not been quite relevant. He did not object to that, but, though he would be only too pleased to furnish them with all the information in his power on the subject of swine fever and anything else, if he entered into a discussion of everything now he would not finish that evening. He therefore proposed to put aside that part of Mr. Gold's criticism which was irrelevant to the paper, but as there was perhaps some little analogy between the position of an inspector dealing with anthrax and one dealing with swine fever, so far as as the Board of Agriculture's Orders were concerned, he would not pass it over altogether. He understood the chief point in this respect raised by Mr. Gold was, that it was a great hardship to a local practitioner for a man to be appointed as veterinary inspector to operate in the district covered by another man's practice. He (Mr. Stockman) might not like it himself, but surely someone must be responsible, and unless they were prepared to adopt the only alternative, and appoint every man an inspector in his own practice, the present system of appointing certain men for certain districts must continue. He did not think it would be a good thing or practicable to appoint every man an inspector in his own practice, because, however anxious a man might be to do his duty, when the interests of the public clashed with the interests of his client, there was just the possibility that the public interest might suffer. If a man did not look well after the interests of his client he would soon lose most of his practice, and he would be worse off than ever through being a veterinary inspector. No one regretted more than the Board of Agriculture the necessity of sending a man to another's district when friction or unpleasantness of any kind arose, but he did see that these were bound to arise, and he saw no way out of the difficulty.

With regard to Mr. Gold's points on the subject of diagnosis, he gathered that Mr. Gold considered the diagnosis of anthrax an easy thing. He (Mr. Stockman) thought it was not always so easy, and he examined something like five thousand specimens a year. There were cases in which there was a distinct difficulty. There were few, if any, general practitioners who had facilities for handling material or who saw enough cases to make them experts, in the sense that he (Mr. Stockman) and assistants at the Board of Agriculture had material, and yet the diagnosis of anthrax was not always an easy matter to him and his assistants. Indeed, he knew from experiment there were many trained county bac-

teriologists who made frequent mistakes, because they did not fully understand the diagnosis of anthrax under the conditions obtaining in practice. Another point raised by Mr. Gold was that the veterinary surgeon was supposed by the Order to take his microscope with him, but as a matter of fact he need not do so. There was nothing in the Order which said he should, but personally, if he were a veterinary inspector he would take his microscope with him. Given a case of undoubted anthrax, which they went to early, in the majority of cases in cattle they ought to be able to say so at once, though there might be an odd case which they could not determine without the aid of laboratory tests, that is assuming the veterinary inspector was skilful. It was surely worth something to be able to say at once whether it was anthrax or not.

With regard to the disposal of carcasses and what had been referred to as police interference, that all depended upon how the Order was interpreted. If a policeman misinterpreted the Order, the Board of Agriculture could scarcely be blamed. He must believe that such interference as had been mentioned did sometimes arise, but the order laid down that the carcass must be disposed of as soon as possible, and the veterinary inspector who took his microscope to the case could often decide if the carcass was to be destroyed or sent to the knacker. There had always been trouble about the burning, etc., of carcasses. A local authority naturally did not want to spend money on it, and carcasses in the past had been left waiting for days while something was decided. The public very naturally complained about this, and the Board of Agriculture had since tried to meet the case by making the Order clearer. A veterinary inspector had only to say he suspected anthrax and the local authority had to destroy the carcass. If there was any undue delay in the burning of a carcass, the veterinary inspector had the remedy in his own hands. He could complain to the Board that his orders were not being carried out. Mr. Gold had asked him whether recovery ever took place in cattle and sheep when the diagnosis was really certain. He (Mr. Stockman) believed it did, but he did not believe that any animal, once its blood stream was invaded by the anthrax bacillus, ever recovered. Even if they took cattle, they would find a definite diagnosis difficult, if not impossible, until the patient had at least reached a moribund state. Given no invasion of the blood stream, however, it was possible for animals to recover, and if at this stage they were given an injection of serum recovery was almost certain. He did not think they would find anything in his paper, as Mr. Gold seemed to think, that they could find the bacillus of black-quarter in the blood prior to death, but there was often an invasion of the blood stream by the black-quarter bacillus after death. He thought Mr. Gold had misinterpreted the meaning of the malignant oedema being found in blood smears. He (Mr. Stockman) did not think malignant oedema as a disease was found in cattle except under the most exceptional circumstances, but even if malignant oedema was a disease in cattle, they would not find the bacillus in the blood before death, no more than the black-quarter bacillus, because these organisms were obligatory anaerobes, and could not multiply in the blood stream till after death. The point about the malignant oedema bacilli was that they were natural bacteria of the intestines and invaded the blood vessels after death. Indeed, he would go so far as to say that in almost any carcass, if it were left long enough, the bacillus of malignant oedema would be found. As to what Mr. Gold referred to as the failure of the M'Fadyean reaction with cultures, it was a very elementary piece of knowledge with regard to the anthrax bacillus that when it was taken from the blood it had a capsule, and when taken from a culture, unless serum was the medium, it had not; and in that fact lay

the answer to Mr. Gold's point, because the capsule was concerned in giving the reaction. As to whether it was necessary to shut up a whole shed owing to a case of anthrax, as Mr. Gold said, it was a matter for discretion, the Order said all places contaminated. Whatever part had been exposed to infection should be shut up, but if proper precautions had been taken it should not be necessary to close the whole shed of a large byre.

With regard to Mr. R. Over's point, he did not know whether it was intended as a complaint that he had told them nothing new which would enable them to diagnose anthrax during life; he would have done so if he could, but the fact remained that one had to suspect anthrax during life by the history of the case, and symptoms which were not diagnostic, as there were no definite means of diagnosing it until the patient was beyond their help, through a previous case and certain symptoms would be almost convincing. Where anthrax was suspected, but everything had been done to exclude it, he did not think there could be any exception fairly taken to a man conducting a post-mortem examination in cases of sudden death; all the Board asked was that reasonable care should be exercised. He certainly did not wish to assume that the Board and Professors at veterinary colleges were the only authorities on anthrax, but there were not many men in this country outside veterinary institutions who had had the opportunity of becoming experts in the diagnosis of the disease, as met with under the conditions of practice and who were versed in laboratory methods. If a man was going to err at all, he generally wanted to err on the safe side, and said it was a case, if he suspected it of being anthrax. Probably he (Mr. Stockman) would do the same if he were placed in the same position as a practitioner, but as a man responsible to the Central Authority and whose advice might lead to the expenditure of large sums of money for the prevention of the spread of the disease, it was incumbent upon him to base his statistics upon something more reliable than mere opinion, opinion which everyone agreed, varied in value according to the man who gave it.

Dealing with a point raised by Mr. Brooke, he said it was common knowledge that, at least in towns, the majority of cases of anthrax in horses were due to infected grain. In fact, one could often trace one or two outbreaks to a special consignment of oats. Mr. Brooke expressed surprise that the paper, in stating particulars of counties where anthrax was most prevalent, did not mention a wool-washing county like Yorkshire. He would like to point out that the table of counties only dealt with the five worst infected counties. It took a great deal of time to prepare statistics of the kind, and he had only given the most typical counties to illustrate his argument. He could not help Mr. Brooke as to the diagnosis of anthrax in horses, where there was nothing but colic, but if there was swelling of the throat as well, it was pretty certain to be a case of anthrax.

Mr. MARTIN: In the last case I saw there was no colic.

Mr. STOCKMAN: I do not say there must be colic, but it is a common symptom. A suggestion was made that he had taken too little account of how far flies were responsible for the spread of the disease among human beings. He did not deny that flies were a possible medium of infection, but he thought they might be considered a negligible quantity in epizootiology, and so he had given them little prominence in his paper. A man who was working amongst wool might make a scratch upon himself so small as to be seen by no one, or he might inhale spores. As to the value of serum for producing lasting immunity, it only gave immunity for ten days, and as it cost something like half-a-crown or more adose, it would not be very cheap to keep on giving an animal that amount of serum every ten days throughout its life. The great value of serum was in the immediate

protection it gave to animals which have been exposed to infection, or which are exposed to a risk lasting only for a few days.

Mr. R. OVER asked whether serum had been tried with success on man.

Mr. STOCKMAN answered this question in the affirmative. Continuing, he said there were many countries known to suffer a great deal from the ravages of anthrax, and if they followed the importation of food stuffs they would be able to trace a series of outbreaks apparently from food stuffs that came from those particular countries. That had been apparent in the case of Soya beans, which was a comparatively new food stuff in this country, and came from an anthrax country.

He was disposed to agree with Mr. Devine as to the small value to be derived from the taking of an animal's temperature, but was it of diagnostic value in any disease? One would hardly like to visit a case without taking the temperature of the patient, but the only value of a temperature was to make them suspicious. The temperature was not likely to tell them what the disease was, but it was a detail in diagnosis which could not be overlooked. Mr. Devine said he had always found the bacilli of anthrax in the horse's blood, and whilst, of course, he must accept that statement, he had to say that it had not been his (Mr. Stockman's) experience. With regard to the value of methylene blue, it must be remembered that these dyes varied in composition according to the manufacturer. At the laboratory of the Board of Agriculture they had always had good results with methylene blue, properly used. However, it should be remembered that if the bacillus is taken fresh from the blood immediately after death, one did not expect to get the reaction in a marked degree.

With regard to Mr. Martin's remark as to the opinion of Prof. McCall, he felt inclined to accept it as correct, especially as it had been backed by Mr. Martin's own experience, but it was a matter that was beyond his explanation, unless it was that an accumulation of spores took place at the bottom of a bin. As to what precaution should be taken in the case of a milking herd after a case of anthrax, so long as the bacillus was not in the blood stream he did not think it would invade the milk glands. The moment the bacillus entered the blood stream the animal would become in a moribund state, and certainly too ill to be milked to supply milk for food, even although anthrax was not suspected by the owner; but given a case of anthrax in a dairy herd, the temperature of all cows should be taken, and the milk of those showing a distinct rise should be excluded. As to the Chairman's point about practitioners being done out of business by inspectors being brought in from other districts, he had already tried to answer that question. He offered the suffering practitioners his sympathy, and if a better way of doing things could be suggested by the profession he was sure the authorities would listen to it. The Chairman also objected to the veterinary inspector's diagnosis being accepted in preference to the local practitioner's. The reason was that someone must be the judge, or there would be no finality. It did not necessarily follow that the inspector was always right, but he put it to him as a veterinary inspector if he would like to have the practitioner's diagnosis accepted before his own. There was only one centre to refer cases to officially, and that was the Board of Agriculture, although he understood local authorities did ask for material to be sent to other places as well, and, of course, there was no harm in that. As to the police coming on the premises, the police were a much abused body of men, and he thought any veterinary inspector present would agree that the police were very useful in cases of contagious disease. They did a lot of necessary work which a competent veterinary inspector should feel it *infra dig.* to do himself, and to do the policeman justice, it must be admitted that he was ren-

dering the authorities charged with the suppression of disease very signal service. He had no sympathy for the veterinarian who wanted to do police work, it was not his job. As to the Chairman's question about the value of vaccines in Canada, he would not like to offer an opinion. Canada had a good veterinary department of her own, and as he was not familiar with the country and its special circumstances he would rather not offer any advice. Mr. Stockman concluded by thanking the meeting once more for the kind manner in which he had been received and his remarks listened to.

The PRESIDENT moved a vote of thanks to Mr. Stockman for his paper, and especially for his coming down a second time to answer the discussion.

Mr. GOLD, in seconding this, said he would like to take the opportunity of assuring Mr. Stockman that his criticism, though perhaps a little severe, was not intended in a personal or even in an unfriendly sense, and he hoped Mr. Stockman would accept his assurance as to that.

The vote of thanks having been very heartily carried, Mr. Stockman said, in acknowledgment, that he had enjoyed the criticism, and in trying to hit back a little he had been actuated by an equally friendly spirit.

CHONDROIDS IN THE GUTTURAL POUCHES.

Mr. WOODWARD introduced an interesting case of chondroids in the guttural pouches, and produced specimens for the information of those present. He said the subject was a bay cob mare, aged seven years. She was bought eight weeks ago, and had a swollen throat at the time of purchase. The mare had been treated for strangles for three weeks, and her throat poulticed without any relief. Her appetite was suspended and no food had been taken for five days prior to her being seen by Mr. Woodward on August 1st. The mare was then very much swollen over both parotids and under the throat. The swellings were firm and hard, the temperature normal, and the pulse weak and thready, with a marked jugular pulse. The mare was unable to swallow anything, water being returned down the nostrils, and from the near nostril there was a thick nasal discharge. On August 2nd, the throat was blistered and the conditions were unchanged. On August 3rd, the mare was breathing with much difficulty, and the swelling over the parotid on the off-side was explored with a trocar and canula, only a bead of pus appearing. He cut down on the parotid swelling, breaking through the tissues with the fingers, and extracted 48 chondroids. The swelling was greatly lessened and the breathing relieved, the patient being removed to the infirmary. The dietary ordered was oatmeal gruel and eggs, and bran mash, the appetite being good. The guttural pouches were syringed out through the wound with a solution of Permanganate of potash twice daily, the solution being freely extruded from both nostrils. Belladonna was also used frequently during the day. Between August 3rd and 5th, 74 more chondroids were removed, being loosened from their attachment by the syringing, and brought away by means of Hobday's obstetric forceps for the bitch. Altogether, 113 chondroids were removed. They weighed collectively 26 ounces, the largest weighing 6½ drams. There was also a pint of thick cheesy substance, containing great numbers of greyish-white grains, similar in character to the material forming the outer coat of the chondroids. The mare was now well on her feed and he hoped to be able to record a recovery.

The HON. SEC. moved a vote of thanks to Mr. Woodward for his kindness in bringing this very interesting case forward, and at the same time took occasion to remind members that at the next meeting of the Association the discussion would be upon such cases as were brought forward by the members themselves which they had come across in the course of their ordinary practice.

The PRESIDENT seconded the vote of thanks, which was carried.

THE INTERNATIONAL VETERINARY CONFERENCE.

The HON. SEC. said that as Mr. Stockman, who was the Hon. Sec. of the Reception Committee was present, he would like to raise the question of the International Veterinary Conference which was to be held in London in 1914. Perhaps Mr. Stockman would tell them something about it.

Mr. STOCKMAN said that a good deal of money would have to be raised if the delegates from abroad were to be entertained in a manner worthy of the profession. In other countries the Government generally found a good deal of money, or at least did much of the entertaining, but he did not think they would get anything from that quarter in this country. Any member of the profession if he gave them a subscription might have a seat on the Committee, and they would, indeed, be glad of the services of anyone who had the time and the inclination to serve in that capacity. Some gentlemen were contributing so much a year for the next three years, and that was perhaps an easier way in the long run of helping. He need hardly say he was looking to the Midland Association to give them substantial assistance. He hoped to see local committees established.

The HON. SEC. said they had a good balance at the bank, and he thought they might contribute something towards the expenses of the International Conference. When the Conference had been held in other countries the entertainment had been on a very generous scale, and for the credit of the profession in England they must all make an effort to ensure that the London Conference did not suffer by comparison. He undertook to place the matter upon the agenda for the quarterly meeting, when a Committee could be appointed to take the matter in hand.

The meeting being ended, the members had tea together before separating.

H. J. DAWES, F.R.C.V.S., Hon. Sec.

CENTRAL VETERINARY ASSOCIATION OF IRELAND.

A meeting was held at Buttevant on the 12th July. Mr. J. F. Healy presiding.

The minutes of the last meeting were read and confirmed.

The SECRETARY read a letter from the Secretary of the Local Government Board, Ireland, which was considered unsatisfactory, and it was decided to ask the aid of Parliament to obtain the desired end, *i.e.*, to secure that only an M.R.C.V.S., where available, should hold Inspectorships under the Dairies, Cowsheds, and Milkshops Order.

The Secretary read letters from Mr. Gofton *re* the proposed Amalgamation of Veterinary Societies. It was decided not to take any action in the matter.

NOTES ON CLINICAL CASES.

By E. A. PHIPPS, M.R.C.V.S., Bandon.

RADIAL PARALYSIS.

A well-bred two-year-old filly was standing on a hot summer's day at a gap, switching flies with her tail, when the tail got caught in a bush, she galloped madly away, and was seen in the field shortly after, showing the following symptoms.

Symptoms.—Dropped elbow, typical case, very marked, flexion of joints of limb, swelling severe over region of shoulder and around elbow and forearm, no crepitation

of any description. Owner suspected fracture of humerus. Prognosis fairly favourable.

Treatment.—Very hard to get mare to walk some 300 yards or so to yard. Placed her in a large loose box, and had a good bed of sea-sand put down (the summer bedding used on the farm). Complete rest and quiet ordered. Shoulder fomented several times daily and mild lin. alb. applied. With the exception of nervousness (untrained filly), good patient. Slight improvement seen in three weeks, and then gradually for six weeks or so. Wasting of the scapular and caput muscles occurred. Blistering and walking got mare perfectly restored within six months. This mare I showed to the late Mr. W. A. Byrne, indeed he examined her for a nomination, and he seemed surprised at her rapid and complete recovery.

FACIAL PARALYSIS.

Subject.—An aged mare.

History.—Supposed glanders. Marked nasal gleet—probably due to injury.

Treatment.—Usual adopted, but of no avail, as the origin was undoubtedly central. Is it of any use to treat paralysis due to central causes?

PROLAPSE OF BOWEL THROUGH INGUINAL CANAL.

Subject.—A seven-year-old gelding, belonging to same owner.

History.—Remarkable. Horse was apparently quite sound; was sent to forge, and the boy was then sent riding him, for a bar of iron such as shoes are made of. Coming home, horse took fright under railway bridge, boy dropped iron bar (about 6ft long) which he held in his hand. The horse galloped on, and was seen to fall. On being called out I found the following.

Post-mortem.—Prolapse of small intestine through inguinal canal, for about 18 inches. Clean cut of say, 3 inches over canal, no laceration—canal uninjured apparently—practically no hæmorrhage, and was told there was no blood on road or on bar. Now this, to my mind, is of great interest. How did the bowel become prolapsed? It certainly looks as if the bar had punctured the skin and penetrated inguinal canal, but there was no laceration of any kind and the canal seemed perfect.

MONSTROSITY IN CALF.

A three-year-old heifer calved quite naturally, a first calf, which presented the following appearances:

Fair sized calf with marked hydrocephalus, head greatly deformed—two heads apparently being fused into one: probably an aborted effort at twins. There were four eyes, two noses, absolutely perfect in formation, apparently no upper lip, and tongue protruding. A hermaphrodite. It was very strong, except the head was too heavy, and would fall forward. I shot the calf, apparently through the heart, but he got up afterwards, and I had to give him a second barrel the other side. Had he two hearts? Owing to circumstances had to do away with him without a post-mortem.

GROWTH AROUND ŒSOPHAGUS OF COW.

The subject, an aged cow, showed no external swelling. Animal healthy, and very hungry, but wasted. Drink *ad lib.* could be taken, but any solid food just on entrance to stomach was forced back. Diagnosis—growth. On suggestion of Mr. E. Wallis Hoare, passed probang. Could not enter the stomach. Post-mortem—tuberculosis.

FRACTURE OF CARPAL BONES.

Subject, a six-year-old cob gelding, had fallen when galloping around hard field—a very heavy fall. Very marked lameness, superficial wound. Distinct crepitation, apparently in centre of knee, swelling not very great even 12 hours after. Could not possibly locate exact fracture. Treatment not recommended owing to

certainty of stiff knee. Let him take his chance. The first case of simple fracture I have seen in knee. Now nearly three months after accident, pony still going about on three legs—no improvement whatever.

OPEN WOUND IN HOCK JOINT?

Subject.—A two year old filly, own sister to "Rock-dove."

History.—A very slight (apparently) scratch seen on hock, and usual Jeyes fluid, etc., applied. About a week afterwards hock showed great swelling, and the inflammation was intensely painful and severe. Owner wired for me, and I found filly literally in agony.

On examining the hock very carefully, I found a slight scar on outside, just about over seat of joint, removed this with my nail—did not use knife or probe, owing to location of injury. Took mare's temp., etc., and found it 102. Put patient in slings, and applied Bellad. and glycerine, B.P., and anti-phlogistin, covered same with wool, and bandaged. Gave Mag. sulph. and pot. nit. in mashies. Mare continued in great pain, and I repeated treatment. Appetite very good, temp. up to 104; urine and faeces normal. On examining hock in a few days' time something which I took to be pus seemed to squirt out of wound. On flexing hock synovia and pus squirted out. I again used same treatment.

After some days, on being satisfied wound was clean, I blistered round the opening, but to my disgust the wound refused to close, although I used the cautery. Having heard of slaked lime being of service I applied it, and it completely fulfilled its purpose. For three weeks the mare remained in slings, and suffered a great deal, but being healthy and appetite good recovered. The hock remained large; it was blistered. She was turned out about five weeks after and again blistered. In a week or so after she got a relapse of inflammation, but the original treatment being adopted she got all right immediately. Repeated blistering failed to reduce swelling, which remained like a bog spavin and thoropin, although she gallops quite sound. I think the hock joint may have been affected, but of course it may have been some smaller joint. Am certain it was not only the tarsal sheath. The small visible wound makes the case unusual.

SEVERE INJURY TO HOCK.

Case I.—Subject. A 4 year old farm mare.

History. A punctured wound (cause unknown) on inside of hock, seat of thoropin. Had worked even after this was seen, and then went sound. Two days later synovia in plenty, and great inflammation. Used anti-phlogistin and Bellad. and glycerine. Lime practically closed the wound. Temp. up. Very great pain—not put in slings, as she would lie at first. Sweating. Febrifuges given. On examining hock after five days found very distinct crepitation—quite audible, and on seizing point of calcis, and metatarsal bone could get great mobility.

Post Mortem. Fracture of astragalus.

Case II.—Farm mare 4 years old. Opening of tarsal sheath with barbed wire—a long lacerated wound in front of hock, and to inside; synovia oozing freely. Corrosive sub. 1:1000 used and lime applied as antiseptic. Lime efficacious. What is its action? Complete recovery in a week; inflammation subsided quickly—no poulticing in this case. Wounds from barbed wire are, in my experience, very liable to that distressing sequel, tetanus.

INJURY TO MARE'S UDDER.

An aged farm mare, in lactation, was brought by her owner into infirmary with a scratch on udder—he did not know how it had happened. I, foolishly, said it was a matter of nothing, and adopted stupes and antiseptics. Later on owner called me out; there was a large abscess

in udder, temp. subnormal (probably) fluctuating, oedema along belly and inside thighs, cold sweat. Opened abscess, liberated quantity of pus, syringed out with lysol and after with tr. Iodine 1:2.

On calling in two days' time, found mare with udder stitched, and very sore and stiff (a quack relation of owner had come there) told that "farcy" was the root of the evil—mare blistered on shoulder which Mister "Quack" had said was "farcied." On turning mare round owner said that he was told that if the mare moved, her bone would break. Mare died.

This case speaks rather against myself, and only shows how very careful one should be in giving an opinion, even in apparently simple cases.

STRYCHNINE POISONING.

Subject.—A strong 2 year old fox terrier.

History.—Probably distemper. Symptoms, Chorea.

Gave Easton's Syrup in teaspoonful doses in solution. First dose took dog so badly that owner destroyed him during the spasms. Moral—don't use strychnine, although some dogs will stand a lot of it. This is not my only experience of the danger of this drug to dogs. Luckily owner was a great friend, and knew the treatment, etc.

CASES SHOWING BRAIN SYMPTOMS.

These cases are remarkable in that they occurred on adjoining farms. The first was a case in an aged mare, which showed marked evidence of brain trouble—complete blindness, would knock head against wall, etc., temp. subnormal, and pulse thready. Suspected stomach, and gave purgatives and nux vomica, also heart tonics and stimulants. Complete and rapid recovery.

History would point to digestive trouble; the faeces mucous coated and very offensive.

Two in-calf heifers in the adjoining farm, living on grass, about the same time shewed symptoms of Meningitis: would reel about and fall, glaring look in eyes, dilated pupils, very sensitive to touch, mucous membranes injected, and sclerotic markedly so, temp. up 3 or 4 degrees, and pulse small; stertor; lying down. Salivation, violent spasms, followed by coma and death.

Gave purgatives and P. Br.

In one cow—hyperaesthesia, dilated pupils. In the other—stertor, staggers, marked dilation of pupil, coma and death.

Post mortem. 'Tuberculosis.

In a case of this kind the previous year on the same farm the post mortem was said to reveal injection of the meningeal blood vessels.

It may be only a coincidence—these cases occurring together in same district, but it is quite sufficient to arouse one's curiosity. The grass, etc., on farm is very good.

PROLAPSE OR INVERSION OF UTERUS IN COWS.

This trouble is very common in my district; there is difficulty in returning the organ. I had one quite successful case, with amputation, in an old cow which had the uterus out for two days. I put on the tourniquet, and Staffordshire knot with iodoform tape (pack needle); to the stump applied astringent and antiseptic powders and administered whiskey, etc. No further treatment was required and she never looked back. In other cases death has occurred from shock. I would feel grateful for any hint as to the successful reposition in these cases, for I must candidly admit that in most cases they fail me. After how long may successful return be accomplished?

PURPURA HÆMORRHAGICA.

Subject. An aged farm mare with foal at foot.

Apparently a case of strangles—Smith had lanced jaw, foal had developed strangles.

Symptoms.—Hind leg had greatly swollen—typical cord like marking near burb end, same also under belly, on neck, and on shoulder. Marking on pin, and petechiæ on sclerotic and conjunctiva—pulse slow and soft as in influenza. Temp. 103-105 F. Appetite capricious. Prognosis—unfavourable.

Treatment.—At first give febrifuges and Pot. Iod. and Liquor Ferri. perchlor. Mare not progressing, gave Nuclein (P.D. and Co.) one ounce b.i.d. Result, swellings disappeared or nearly so, and appetite improved. Swellings recurring, again gave medicine with good results, swellings disappeared and then reappeared: used 5viii in all. Mare lay down, and stayed down till death in a fortnight ensued. She ate up to the last.

Nuclein, perhaps, if persevered with longer might have given better results.

ŒDEMA IN HEAD OF FOAL.

Called to see foal of two weeks old with great œdema of head, lips and buccal membranes being enormously enlarged. On lancing, a yellow exudate, œdematous fluid escaped, and swellings were very jelly-like. Sent head to Royal Veterinary College, Dublin, and the result arrived at was œdema, probably due to a wound.

The foal was quite all right the night before; in the morning, when I arrived, the head was as described. Treatment of no avail, lived for three days. A large gelatinous clot obstructed the glottis.

FIBROUS TUMOURS IN FALSE NOSTRIL.

Two of these cases were treated, one in a three-year-old and one in a four-year-old. In both cases the tumour occupied the same position as an atheroma. Operated on both cases standing, successfully. These tumours take a long time to dissect out, as they are firmly adherent to the skin, and subjacent structures. They were about the size of a duck's egg.

Injected adrenalin and cocaine in one case as I found the danger of getting struck with foreleg was great. Also, it is difficult, on account of position of tumour, to keep head steady.

The three-year old was only haltered and was untrained. A long vertical incision was made, the tumour cut in halves, and dissected out. The cavity was then washed out with sublimate and iodine, sutured, and healed rapidly, and no blemish except a tiny scar, in one case hardly perceptible. What is the cause of these growths?

Messrs. Howard, Mulcahy, Healy, and Winter took part in an animated discussion on the paper, and the meeting then adjourned.

E. C. WINTER, Hon. Sec.

"A Horse Doctor for Asses."

Not merely once and again but many times have the bombastic pretensions of Tuberculozine to cure consumption been exposed in *Truth*. The stuff has also been analysed and the results of the analysis published in "Secret Remedies," showing that this so-called specific is nothing more than a bromide and glycerine mixture of no value for the inhibition or destruction of the tubercle bacillus. It has been pointed out that the labels, the advertisements, and the descriptive literature published to push the stuff in this country vary from those used in the United States, where it is necessary to be more guarded in making unprovable claims in regard to a quack medicine if a "fraud order" is to be avoided. Yet despite all exposures the portrait of "Dr." Derk. P. Vonkerman, of Kalamazoo, Mich., posing as the discoverer of this "wonderful cure for consumption" still stares at one from the advertisement columns of half the daily and weekly press of Great Britain.

Hitherto my knowledge of this public benefactor has been confined to such account as he gives of himself in the pamphlets puffing his discovery. In these, as in his advertisements, he describes himself as a "Dr.," though displaying a discreet reticence as to where and when he obtained his medical degree. A similar reticence was displayed when by way of counterblast to "Secret Remedies," a Southampton gentleman published a booklet containing replies received to inquiries addressed to the proprietors of a number of widely advertised quack remedies concerning their originators. The reply of the Yonkerman Company was as follows:—

"The originator of this remedy is Dr. Yonkerman, whose medical qualifications are all American. Realising the prejudice in England against doctors with Transatlantic degrees, he thinks nothing would be gained by discussing the same."

I am not aware of any particular prejudice existing in this country against doctors possessing bona fide Transatlantic degrees, but information recently published by the American Medical Association enables me to make a shrewd guess as to why Derk P. Yonkerman stands to gain nothing by discussing his medical qualifications. In the first place, he is not a licentiate of the State in which he practices. In his pamphlet he claims that he "graduated from Ontario College, Toronto, Canada." There is no such college. There is, however, an Ontario Veterinary College at Toronto, and as it happens a Derk P. Yonkerman graduated from this institution in 1882. Yonkerman claims also to have pursued his studies at Stuttgart University, Germany. There is no such university. But again there is a veterinary college at Stuttgart, and though no one of the name of Yonkerman

graduated or matriculated at this college he may well have spent some time there. Finally, in the list issued by the Michigan State Veterinary Board, the name of D. P. Yonkerman, of Kalamazoo, appears as a registered veterinarian. He is, in fact, a qualified horse doctor, and it is on the strength of this qualification presumably that he sets himself up to cure the tuberculous inhabitants of two continents. Evidently Yonkerman is not likely to gain anything by discussing the value of his medical degrees, but it may be otherwise with the public. Of course, if they prefer to allow themselves to be exploited by a Kalamazoo horse doctor they are at perfect liberty to do so. But the fact should be made perfectly clear to them. In this country the M.R.C.V.S. does not call himself "Dr.," and the gentlemen who have specialised in the diseases of animals do not claim to be able to treat diseases of human beings. Nor if they did would they find many patients willing to place themselves under their charge and swallow their boluses. And if the facts were known, it seems hardly likely that a horse doctor from Kalamazoo would be more successful. But, of course, it may be that Derk P. Yonkerman looks for his patients chiefly among asses.—*Truth.*

The Foot-and-Mouth restrictions withdrawn.

The Board of Agriculture and Fisheries made Orders on Monday withdrawing as from Wednesday all the restrictions which were imposed by them on the movement of animals in connection with the recent outbreak of foot-and-mouth disease at Udimore, near Winchelsea, Sussex.

REVIEW.

MEAT AND ITS INSPECTION. A Practical Guide for Meat Inspectors, Students, and Medical Officers of Health. By ARTHUR R. LITTLEJOHN, M.R.C.S., L.R.C.P., M.R.C.V.S., D.P.H. Demy 8vo. Pp. xij+399. Thirty-two illustrations. Price 10/6 net. (Baillière, Tindall, & Cox, 8, Henrietta Street, Covent Garden, W.C.)

This work is intended to serve, not as a complete text book, but as an aid to those practically concerned with meat inspection; amongst whom the author, in his preface, specially mentions meat inspectors and candidates for the Public Health Diploma. Consideration for readers of the former class has led to the work being couched in as simple terms as possible; and upon the whole the author has succeeded fairly well in this direction. As might be expected, however, there are portions of the book which can scarcely be fully followed except by qualified veterinarians and medical men.

Less than 230 pages of the work are original. The remainder consists of the verbatim reproduction of legal documents, or portions of them, bearing upon meat inspection and allied subjects. A large number of these—Public Health Acts, Regulations, Model By-laws, Board of Agriculture Orders, etc.—are quoted in more or less detail; and though their inclusion in one volume certainly facilitates reference, it as certainly sadly encroaches upon the author's space.

In the original portion of the work, the author has attempted to cover a vast amount of ground. Methods of slaughtering, and of dressing and preserving carcasses, the normal carcase appearances and dentition of animals, the physiological conditions which render meat unsound and the commoner pathological changes encountered in meat inspection, some general and special diseases, and also some of the more important parasites and the lesions they cause, are all dealt with in more or less detail. The teaching throughout carries the well-known rule of "if in doubt condemn" to an extent which might be difficult to follow in practice, but this is certainly erring on the right side.

That the treatment of every portion of the book is far from exhaustive, and that some subjects not without claims to insertion are omitted altogether, was of course inevitable; but upon the whole the author has selected his matter and apportioned his space judiciously, and written throughout with lucidity and concision. The work is not free from some inaccuracies.

Taking the work as a whole, however, it must be pronounced a welcome addition to the English literature on meat inspection, which will be found very useful by meat inspectors, students for the meat inspectors' examination, and—perhaps in a lesser degree—by medical officers of health and students for the D.P.H. In the very likely event of its attaining a second edition we hope to see the original portion considerably extended in many directions, perhaps most of all in that of anatomy. As it stands, it is a good book holding the germ of a better one.

W.R.C.

The "Arnoline" Culture for the Extermination of Rats.

Messrs. Arnold have brought out a new rat poison which is alleged to be harmless to other animals, but destructive to the rodent.

"It is acknowledged that all rat poisons and virus up to the present time have failed to exterminate this great pest. After some years of experimenting a bacillus has been discovered that should solve this great problem

of how to exterminate rodents. Before placing it on the market, it was put to the most severe tests, both here and on the Continent, during the past four years, and exhaustive tests have been made, both at the Bonn University and by a leading bacteriologist in this country and certificates have been given to prove that the process is effectual and harmless to human beings and animals other than rats.

It is a well-known fact that with existing poisons and virus a large number of rats become immune, and their offspring are also immune—possibly many people are not aware of this fact—it has therefore been necessary to guard against this fatality, so two tubes of culture are used. Culture A, which is given first, and Culture B, to kill off any that may survive. The first is given as a food, and then, should any survive, one should be caught and a small quantity of the second tube dissolved and injected under the skin by means of a hypodermic syringe, and then let loose to run with the others, who will become affected and die. This should be done by a veterinary surgeon or one used to handling rats."

CORRESPONDENCE.

SHEEP AND WATER SUPPLY.

Sir,

I thought when I read the discussion on Prof. Craig's paper that it would be a wonder if somebody did not take up the opposite view concerning the camel-like proclivities attributed to sheep.

We often criticise the remarkable conclusions of laymen, but here is a practical man writing in your issue of August 18th and playing the same game off on two of our men. Evidently "Kerry Hill" knows more than the gentleman who recently gave his views on worms in sheep.

If sheep don't suffer from lack of water how is it that droughts produce so much disaster on Australian sheep farms?

Whether folded, housed, or at pasture, sheep should have access to water, and if it is not naturally present it should be taken to them. When on dry food in dry, hot weather they need it especially. If two flocks exist side by side, one of which is regularly watered and the other receives no such attention, the difference will soon become apparent. Moreover, they should have good water because this will be the best preventative against drinking from a contaminated source if such be accessible. Of course, when on food containing a great percentage of moisture they are

not eager after water, but for the production of good mutton, digestion, wool, and milk a good water supply is as desirable as necessary. To say that a sheep does not drink water because it lives on Kerry Hills is to forget the pranks of Nature in her wilder moods. We sometimes live in towns and cities so long that we forget our geography and all about nature and the country.—Yours faithfully,

G. MAYALL, M.R.C.V.S.

A WONDERFUL PROFESSION.

Sir,

Having been a reader of *The Veterinary Record* for years and years, and having partially digested the little "twiddleley-bits" which appear so frequently therein, I find, after a long practical experience, to use a racing phrase—they don't come off. I started at the beginning of the profession, served a pupilage for which a heavy premium was paid, and at the termination thereof received a testimonial as to ability, sobriety, integrity, and as to being a fine horseman across country. I then received my membership diploma without having been stopped once, although I may mention that I did not receive a waggon load of medals. Highly elated and inflated, and after advertising in *The Veterinary Record*, notably to the benefit of that organ, I at last received a likely answer, portion of the text of which I beg to produce here:

"Sir,—In answer to your advertisement I am in want of a qualified man. I have a town and country practice and being a bachelor I should require a married man with no encumbrance, the wife to act as housekeeper. I keep a little girl to do the rough work, and should require the wife to cook and superintend the household. The salary I offer is 25/- weekly and all found" Not having ventured to reply to this I cannot say whether the washing was sent out or not.

The offer I accepted as a result of my next advertisement was from a London F.R.C.V.S. as assistant at the princely salary of £2 weekly and rooms found. After a wearisome journey I arrived at the F.R.C.V.S.'s and found the "rooms" to consist of a little cubicle, ill ventilated, and situated at the back of the surgery. The furniture consisted of a folding camp bedstead and a cheap grained washstand. I could not unpack my portmanteau simply because there was nowhere to hang my clothes. Some of your readers will no doubt ask why I stopped in such a place, but the F.R.C.V.S. having a reputation in London, and myself being broke, I decided to lie on the bed I had made for myself, not wishing to remain parasitic on my parents any longer, having entered the profession much against their will. Always being a lover of animals I had decided against their express desire.

The first question I asked my principal was where I was to get my meals. He informed me that there was a place around the corner where his assistants had generally repaired. On going there the following morning the only restaurant I could find was the "Hotel de Lockhart," redolent of soft roe bloaters and festooned with halfpenny "slabs," which I must say were excellent and enjoyable had it not been for the proximity of a huge coalheaver and a peripatetic cabrunner, who had obviously been priming himself from an early hour that morning, and who quite gratuitously informed me that the "cawfee was hextra." With regard to my duties, which were slight, they consisted of keeping the veterinary and forge books, dispensing, washing and dressing dogs, walking and bussing to cases, and not forgetting parcels of medicine for contracts, etc. The business hours ranged from 8 a.m. to 10 p.m., after which I was at liberty to enjoy myself but was expected to be back soon after eleven as the F.R.C.V.S. did not reside on the premises. I stood this for two years. Returning home one night and switching on the light I was genuinely dismayed to see several members of the Order Acanthis scuttling across the snowy pillow towards their lair, having been disturbed by my untimely arrival. This confirmed my own suspicions as well as rumours I had heard. Next day I tendered a month's notice and was earnestly requested to reconsider my decision.

My next move was to the blessed, soul-salving country, with an extremely decent and homely man, who was a

registered practitioner, and who treated me like a gentleman, so that I was in a measure able to recuperate after the experience I had been through.

During my stay in London I met the assistants of several well known practitioners, and I assure you their lot was not a happy one, having been brought up as gentlemen and treated in this abominable fashion, in some regrettable instances they sought forgetfulness of their misery in the oblivion produced by booze. I am acquainted with a practitioner who was assistant to an ex-president of R.C.V.S., F.R.C.V.S., and examiner for the membership and fellowship diplomas. He started at 30/- weekly, out of which he had to disburse 2/6 to the groom's wife for trying to keep clean the "suite of rooms" which consisted of a small compartment over the forge. During the absence of his principal he had to attend Tattersall's, and had to take entire charge of the business, which was at that time returning a considerable amount. When away on holidays, etc., he left explicit instructions that F.R.C.V.S. was on no account to be put on his letters, and to guard against such a contretemps he always left behind a supply of envelopes ready addressed to "So-and-So, Esq." When he died an elaborate obituary appeared in this paper, also a photograph. His many virtues and the good he had done for the profession at large were unreservedly extolled. I would venture to remark that this same paragon employed for a number of years an unqualified man to carry on his extensive practice.

I have lately read that our professional papers are disgusted because of the paucity of clinical notes contributed by practitioners. I must say that I agree with the latter. When a man after years and years of practical experience hits upon a successful method of treatment for certain cases and publishes it in the veterinary papers, a detailed account of it invariably appears the following week in the multifarious publications which cater for stockbreeders and farmers. These "twiddleley-bits" are sent up by so-called veterinary surgeons who gain their experience in garrets.

My sole object in writing this is that those about to enter the profession may be forearmed. In the words of the poet—I have had some.

SAGGITORIUS.

PROFESSIONAL (?) FEES.

Sir,

Your correspondent "Rusticus" very naturally makes an enquiry about a matter the essential details of cost being apparently to him quite unsuspected. As this discussion originated with reference to keep and treatment, the food of the cats and attendant's wage would be comparatively small matters. The greatest cost should be professional services with regard to treatment. A client of a veterinary surgeon when contracting for keep and treatment agrees to pay a sum which would involve total loss to the veterinary surgeon of all other fees in the case. There is a risk, particularly with cats, that the cats may infect other cats with its disease, or contract itself an infectious disease and cause trouble, loss of client, and damage to reputation generally—a really serious matter. Again, fatal or unfavourable termination of an illness in an infirmary involves greater loss of reputation than when it occurs in a client's house, and suspicion of inattention and neglect is much more likely to be aroused. Further, there is the annoyance and loss of time and patience in answering daily enquiries as to how the patient is progressing. I am sure everyone doing an extensive practice in the small animals would support these contentions. "Rusticus" in face of the above would very logically say, "Why not follow my example and decline to take in cats." My answer would be that at the present time, urban horse work being what it is, to refuse to take in small animals would throw the client into the hands of the quack or rival veterinary surgeon. How many can afford to do that? Re matter of keeping or boarding healthy animals, I do not agree with "Rusticus" that there is a conspiracy of silence with regard to the cost. I do not believe that 5 per cent. of veterinary surgeons know the cost. They lump all their receipts, both from professional work and the business of keeping healthy animals, and they might very easily be making a loss on this business and be quite unaware of it. I happen to know the figures

relating to a certain establishment in a cheaper locality than the West end of London, where no professional fees are included, and can assure "Rusticus" that if dogs and cats had been universally charged 5/- all round, there would be a loss each year (only allowing 5 per cent. for depreciation). As things are, higher charges are made and profits shewn at 12½ per cent. It must be remembered that there may be accommodation for 100 animals, but only once a year would there be every part occupied, and during slack times perhaps the number would be reduced to half a dozen.

In the case of veterinary surgeons taking in sick animals separate places must be provided for animals suffering from the various parasitic skin diseases, distemper, etc. And as epidemics vary, a place accommodating 100 might be easily unable to take in more than 40, and then have one or more of its compartments full up. Cats require more attention than dogs. Supposing a Persian is not combed out for a fortnight what would be the remarks of the owner on return who finds her pet a mass of knotted and tangled wool.

I should like to commend Mr. Pope's remarks to all urban practitioners, and they would do well to listen to him. I consider the proposed conference would be valuable alone from its educational effect. The truth is many of us do not know what to charge, and with the awful example of the R.V.S. before us we are turned out into the world as trembling novices, and one hears you cannot get more than 3/6 a week for boarding dogs, and much such nonsense. What are we to believe when the premier institution of the realm only asks 5/- a week for keeping and treating a dog?

Having a dog or cat treated in an infirmary is a luxury, and it is absurd of us to treat as a charity and give our services gratis.—Yours, etc.,

F. O. PARSONS, M.R.C.V.S.

Ealing, Aug. 14.

Sir,

I venture to opine that the righteousness of charging 10/6 per week or more for keeping cats—a sublime subject is it not?—will not be demonstrated by such letters as the latest effusion signed "Vis unita fortior." It may be that such charges really are "just and reasonable"—I am still waiting for evidence upon that point—but neither clumsy attempt at sarcasm nor unveracity will help to prove it.

I have not said, as your correspondent chooses to assume, that "how much an animal costs to keep" was the *sole* consideration in estimating these charges. I did say that it was one essential consideration; and to deny that, as your correspondent apparently attempts to do, is simply to deny the truth. Of course the veterinary surgeon's "skill and trouble" is another consideration, but its importance varies a great deal. When I said that I do not keep an infirmary, I did not justify your correspondent's "conclusion" that I know nothing about them. I have had to do with some, run by men who charged high fees, in which the conditions, so far as the care given to animals was concerned, could only be called disgraceful. This, however, is quite a different point to the one I raised—I asked the actual cost per animal to the veterinary surgeon, and it is very suggestive that your correspondent has not even attempted to answer me.

As for my imputations of spite and stupidity against your correspondent, I imagine that few will now require me to justify them; for his own present letter has done so most effectively. Stupidity!—why, the whole epistle simply bristles with evidence of it. What could be more stupid than to compare the proposed combination of veterinary surgeons to keep the fees up to trades unionism, and to drag in the recent strikes to point the moral? Those strikes were declared to obtain little more than a living wage for the men who actually do the work. The suggested veterinary combination would be to maintain what at least looks very like a system of overcharges, for work chiefly done by the veterinary surgeons' kennel men. The two things are not comparable. Again, could anyone find a more striking example of crass stupidity than your correspondent's unconsciously asinine use of the term "avaricious"? The avaricious man does not do work at any price to keep his neighbour out—and the word "avarice" is better not used by advocates of veterinary rings to keep up the prices.

I imputed "spite"—and mean, cowardly spite, too—to your correspondent, and I reiterate it. No veterinary surgeon who knows anything about dog and cat practice in the West End will have any difficulty in identifying this one "prominent" firm whose infirmary charges are so much lower than those of any other. I neither uphold nor condemn their scale of fees, but I say this. Their action has caused keen feeling for years past in veterinary circles in and around London; but no one really suggests that their patients are worse cared for, or their infirmary less hygienic, than those of their neighbours. One member of the firm, indeed, has individually done at least something to improve the hygienic conditions of veterinary practice. That being so, your correspondent's repeated insinuations of "cheap and nasty" towards them are not difficult to assess at their true value.

The whole question of veterinary fees for cat and dog practice, including infirmary charges, demands more careful and comprehensive study than it seems to have received yet. From a purely business point of view, it is doubtful whether our present high fees are well advised—for it is certain that very many people find them prohibitive. From another point of view, there is something to be said both for and against canine and feline infirmaries, some of which, if the truth were known, would be found no great credit to the profession. The subject is not a quite simple one; and its discussion will not be furthered by correspondents who write merely to advance contemptible individual ends.—Yours faithfully,

"RUSTICUS."

UNPROFESSIONAL CONDUCT.

Sir,

One of the most flagrant cases of the above has recently come to my notice. For some four years a M.R.C.V.S. employed an unqualified man as assistant, who left him and set up in opposition two miles away from his former employer.

This unqualified opponent happened an accident and during his incapacity his cases were attended to by a Major of the A.V.D. Members of the A.V.D. have always impressed me that their conduct was such as to elevate the profession, but what can one think after this. I enclose my card and remain

AN EMBRYONIC VET.

A COMPOUND REGISTRATION FEE— A SUGGESTION.

Sir,

Is it too late in the day to consider whether it is advisable to exempt a veterinary surgeon from paying the annual registration fee of £1 1s., on his paying a composition fee varying in amount according to his age or to his professional life. If so, the amount to be paid might be fixed on actuarial advice. I do not know the average life of a veterinary surgeon, but probably it is not more than fifty-five. If a veterinary surgeon on gaining his diploma paid a fee of 30 guineas, or a practitioner of thirty years of age 20 guineas, of forty years a fee of 15 guineas, and so on in proportion, I believe the R.C.V.S. would be a gainer, because a great number of men paying such fees would die or leave the profession before they reached the age of sixty, and the College would certainly have the money in hand, and if properly invested the money with interest and compound interest would cover all liability. As an alternative suggestion, probably some insurance would take up the scheme and thus relieve the College of all responsibility. It could be left to the discretion of the individual members to choose whether they preferred to pay their fee annually or by compounding it.

What have other members to say to such a scheme as problematically outlined as above? I think it is well worth consideration. I merely offer it as a suggestion. Veterinary Societies should also consider a similar scheme for the compounding of their annual membership fees.—Yours truly,

SCRUTATOR.

 Kirkstall-road, Leeds

Prophylaxis and Treatment of Influenza and all Febrile Diseases of Horses.

INFLUENZA ANTITOXIN VETERINARY (P., D. & Co.), obtained from the blood of horses which have been immunised against influenza, is a remarkably efficient agent both for the prophylaxis and treatment of febrile diseases in horses, particularly influenza (pink-eye, catarrhal fever or shipping fever) with its complications of cough, laryngitis, bronchitis, strangles, pneumonia and purpura hæmorrhagica.

Mr. G. J. Bissell, who maintains a racing stable in Kentucky, and who has had considerable experience in shipping horses, writes as follows :—

"It is now over two years since I started to use your Influenza Antitoxin as a preventive. Since then I have never had a case of influenza. I have shipped young horses from Canada to Cuba and back. Formerly I carried \$16,000 to \$20,000 insurance on my stable of race horses; now I carry very little, although I have in training from twenty to thirty horses. If it had not been for your Influenza Antitoxin I would have certainly given up a racing stable of horses."

J. E. King, Assistant State Veterinarian, St. Louis,

after four years' experience with Influenza Antitoxin, states that it will abort strangles and cause the tumours to gather and discharge in from 24 to 36 hours, and in pneumonia it enables the veterinarian to save 90 per cent. of those grave cases which invariably die under medicinal treatment alone.

G. W. Dunphy, Consulting Veterinarian of the Michigan State Live Stock Sanitary Commission, states :

"Its power to arrest the action of the influenza toxin seems almost phenomenal."

Supplied in Vials containing 30 c.c.

PARKE, DAVIS & CO., 50, Beak Street, **LONDON, W.**

**Next Session commences,
Monday, October 2nd.**

Further particulars may be learned on application to

ROBERT ANDERSON, S.S.C., Sec.
37 York Place, Edinburgh.

THE 'RECORD' PRECISION SYRINGE.

The FINALITY of Hypodermic and Serum Syringes.

"The **'Record'**" Precision Syringe is a piece of delicate mechanical workmanship well deserving its name. It meets **all requirements as regards aseptic conditions and accuracy and it is always ready for use.**

It consists of **metal and glass** only. The glass barrel is ground inside perfectly true to cylindric form. The Nickel vacuum piston is "ground in" into the glass barrel by precision machinery so as to fit hermetically, it slides smoothly, yet tightly, **without any lubricant.**

The cover is fixed on the cylinder with a **bayonet-fastening**; for the purpose of **thorough cleaning** it is provided with a segmental incision, by means of which it can be detached from the piston-rod by sliding it off side-ways. When **completely** taken apart the Record Syringe **forms 3 parts only: cover, piston and barrel.**

The **Needles** are provided with the original "Progressive" **flat** mounts. By this arrangement a good hold is afforded to the operator.

The fixing of the needle itself in the mount, by means of a smooth longitudinal guide arranged above the screw threads prevents the needle from breaking off in the mount.

EVERY SYRINGE IS GRADUATED BOTH IN C.C. AND MINIMS.

Price with 2 Steel Needles in Metal Case—20c.c. 21/- 10c.c. 17/6. 5c.c. 15/- 2c.c. 10/- 1c.c. 9/-

Saloform Pessaries.

The New Uterine Antiseptic

Highly recommended by many eminent
Veterinary Surgeons.

PRICES: Ordinary Strength, White.

4/6 per doz. 48/- per gross.

Extra Strong, Yellow.

6/6 per doz. 72/- per gross.

Sole Proprietors—

HARKNESS, BEAUMONT & CO.,

Wholesale Chemists,

EDINBURGH.

Veterinary Surgeons have for long keenly felt the want of something which could be used with good results as a Uterine Antiseptic and which at the same time could be quickly and easily administered. After many trials, and with the kind co-operation of some able Veterinary Surgeons of great experience in parturition cases, we have succeeded in producing

a Pessary made with a **non-oily base** which does its work efficiently and at the same time is non-irritant—in fact, soothing in its effect. They are of great use in parturition in cows or mares; and if administered immediately after parturition they will keep the Uterus clean and healthy, and prevent the after-birth becoming foul.

Veterinary Surgeons in various parts have highly recommended them, and there is an increasing demand for both kinds.

Customers are requested when ordering to state which kind they prefer.

A RECENT UNSOLICITED TESTIMONIAL.

AINSWORTH WILSON, ESQ., F.R.C.V.S.,
writes:—

"I have used the Saloform Pessaries supplied by Messrs. Harkness, Beaumont & Co., of Edinburgh, with good results in various diseases of the genital organs, both in mares and cows, more especially after parturition. They are particularly useful in retention of the afterbirth, with septic complications. It is often impossible to attend more than once a day to irrigate the uterus; in such cases it is good practice to leave one or two of the "extra strong" pessaries *in situ*. I have found them an excellent substitute for Iodoform and other well known non-irritating antiseptics. I feel justified in recommending them to the profession.

Witham, Essex.

THE VETERINARY RECORD

A Weekly Journal for the Profession.

EDITED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1208.

SEPTEMBER 2, 1911.

VOL. XXIV.

CLINICAL RECORDS.

Bovine monstrosities are common; but the existing records of them are often unsatisfactory. Many of such reports are so meagre in their details that they are of little interest to the clinician, and perhaps still less to the teratologist. Last week we published one by Mr. H. Thompson which was well above the average in this respect; and to-day we print a still fuller one by Mr. A. McTurk. Apparently this gentleman has given some attention to the subject of monstrosities; and he must be congratulated upon the care and skill with which he investigated and described the case in question. His report will interest clinicians, and would interest teratologists also.

In one sense, teratology never will be a study of practical import to the bovine obstetrician. To know the frequency of monstrosities, and therefore to remember the possibility of one in any puzzling presentation, is all that is required from the strictly clinical point of view. The forms these freaks take are so diverse that no directions for dealing with them are of much avail; the practitioner must depend upon his own skill and resource in their delivery. Nevertheless, teratology is a special branch of the great science of embryology, and may become even more important one than it is now. Bovine obstetrics is rich in materials for its study; and a country veterinary surgeon who chose to take up the subject seriously might succeed in doing really useful teratological work.

Veterinary practice, especially perhaps country practice, is full of opportunities for observation, as an increasing number of practitioners seem inclined to recognise. Of late there has been a gratifying augmentation of clinical records in various directions, some of much more general importance than teratology. The gastric disorders of ruminants, for instance, are just now receiving some attention, and few veterinary subjects are better worth it. Few are more important in country practice, none more frequently present diagnostic difficulties, and, in many important particulars, we have still much to learn regarding the principles of their treatment. Whether we learn much in this generation depends upon the practitioners of this generation.

FOOT-AND-MOUTH DISEASE.

Foot-and-mouth disease has appeared again, this time in the Midlands. It is clear that our danger of infection from the Continent is acute, and the proposed committee of enquiry into the possible channels of infection will be welcome. What would have happened to British agriculture this year had it not been for the existing regulations of our Board and the efficiency of its officers?

DISEASES OF THE DIGESTIVE ORGANS IN THE OX.

By G. MAYALL, M.R.C.V.S.

I am glad to read that somebody is taking up the study of "Diseases of the digestive organs in the ox." A state of chaos has existed long enough concerning them. Proper knowledge and the best way of treating them are both in a very hazy state.

In making an attempt to answer some of Mr. Wallis Hoare's questions I claim no originality, but am writing to try to throw some light on the subject and to express a few opinions.

(1) I consider that the state known as *impaction of the omasum* does not arise *per se*, indeed it may be said to be always impacted. The contents of this stomach are ever dry, and competent observers say it has no secreting power. The complaint leading to inaction of the omasum may be called chronic indigestion, and is a gradual process affecting all three stomachs—rumen, reticulum, and omasum. Dry indigestible food is its chief cause, hence we see it here when the pasture loses its succulence and does not contain enough juice, and when, perhaps, along with this there is a scarcity of water. It may be called atony of the stomachs; the French call it "*Météorisation chronique*" and the Germans "*Pansen paresse*."

The present treatment of the complaint in this country is primitive, and almost useless. Rationally, after experience of very many failures with cow drinks, large doses of linseed tea (or as the Germans call it "linseed slime") would seem to be about the best treatment, and lately I have been using a combination of arecolin and veratrin and then strychnin given alternately every two hours in linseed tea, but I have not yet had sufficient cases to form a judgment on the matter.

A German veterinary surgeon claims (comparatively) wonderful results in several hundreds of cases he has treated in this way, and certainly it seems a more rational method than the pouring of many drastic mixtures (I won't call them purgatives, because they often don't act) into bovines, as with us. The medicine, containing the drugs mentioned above, is made up and sold as "*Arecoverol*" in Germany. All solid food is forbidden, and linseed tea used along with the medicine for many days.

(2) *Gastritis* may be due to irregular feeding, unsuitable food, animal parasites and *occasionally*, I think, to impure water or moisture. It isn't always caused by coarse indigestible grasses. Lack of proper chewing and rumination when the teeth are being changed may lead to it. Unsuitable com-

position of rations may be a cause of it. It may be true that coarse ingesta does not enter the abomasum, but true digestion takes place there, and this stomach is as liable to become acutely affected as the same organ with similar attributes in other animals. If starch and proteids are digested in the fourth stomach of ruminants, gradual excess of these, or a sudden great addition to the normal supply, may set up inflammatory changes or at any rate lead to grave disturbance of the digestive functions.

(3) In case of *impaction of the rumen relieved* by our so-called cattle purgatives, the fourth stomach and the bowels get *occasionally* acted on. Possibly this may be due to such irritants as croton beans arriving at the fourth stomach and the intestines. I wonder why the old instrument by which you could inject fluids direct into the rumen and by turning a stop-cock let out the gas, went into disuse. It had its advantages.

(4) "*Spewing of the cud*" is apparently due to indigestion following the giving of bulky inferior food. The rumen, perhaps filled with food of this kind, is also oversupplied at the same time or shortly after with water, and food is brought up into the mouth not of the right consistence to be formed into balls as in normal rumination, and hence is voided and not rechewed and swallowed. At the same time I should opine there is contraction of the rumen and possibly violent or spasmodic lessening of its volume. Both Armatage and Steel mention "dropping of the cud" in their books on the ox.

PROLAPSE OF THE RECTUM IN PARTURIENT MARES,

By C. W. TOWNSEND, F.R.C.V.S.

It was with much interest that I read the abstract upon this complication which was recorded in your edition of July 29th. Personally, I always look upon the condition as being one of the most serious and fatal that we have to deal with subsequent to parturition in mares.

Although this complication, luckily, cannot be described as being common, the high percentage of mortality that ensues when it is met with has often struck me as being both surprising and perplexing.

Whilst I quite agree with most of what Hamoir has written in connection with the subject, I still cannot quite understand why it is that the fatality should be so great when the complication occurs at or subsequent to parturition. Eversion of the rectum is a condition which no doubt every practitioner meets with from time to time, and we do not regard the sequel as necessarily a fatal one, in fact I look upon the result as being generally satisfactory. But in those cases in which the condition occurs at or subsequent to parturition I have only up to the present had one case recovery. I may add that this appears to be the experience of several practi-

tioners to whom I have mentioned this subject. My own percentage of fatalities have therefore been higher than those of Hamoir, who estimates his roughly at 92 per cent. which also seems very high.

In speaking of the causes of this condition, no doubt the violent expulsive efforts of the dam in getting rid of the foetus play an important part in bringing about this sequel, and in most cases I have met with the size of the foetus has been abnormally large. On the other hand my experience coincides with that of Hamoir in that the complication may occur after a perfectly normal parturition and in cases when the foetus has not been abnormal in size.

The author attaches considerable importance to the presence of hardened faeces in the rectum previous to and during parturition as being very likely to cause this condition. It has, however, been my experience that usually with the first violent abdominal contractions of the mother, the contents of the rectum are voluntarily expelled, this taking place before there is much pressure between the rectum and the foetus. Again, at the commencement of parturition the foetus seldom gets into the pelvic cavity, but only at the entrance. I therefore cannot regard the loaded rectum as an important factor in causing the eversion. I am more inclined to believe that the violent abdominal contractions of the mare during parturition, combined with the violent pressure which there must necessarily be upon the rectum during expulsion of the foetus, which latter must exert direct pressure upon the more or less imprisoned rectum, causing acute inflammation, expulsion and subsequent paralysis.

This sequence may possibly explain to some extent why it is that the fatality is so high when this condition occurs at or subsequent to parturition.

Treatment. Although we cannot regard this condition as a hopeful one, some attempt must be made to save the animal's life. Reduction of the prolapsed portion of bowel must first be performed, this is generally easy to accomplish; moreover, it is seldom that eversion of the prolapsed portion recurs, this is no doubt due to the fact that inflammation and paralysis soon set in.

The symptoms mentioned by Hamoir soon set in, and death almost invariably takes place in from two to four days after parturition. The symptom which I regard as being the most favourable one, is continued action of the bowels.

No doubt the therapeutical measure indicated is that advised by Hamoir, viz., resection of the prolapsed portion of bowel, but unless this is done early, before paralysis and necrosis has set in, this treatment is useless. I would like to ask how many owners of valuable mares would care to run the risk of this operation, and more particularly in the first instance.

In conclusion I may say that we seldom find this condition described in veterinary text books, and I would like to know what is the experience of other practitioners, both as regards the treatment they adopt and the results they have obtained.

TUBERCULOSIS OF THE UDDER.

During the course of my duties examining cows for tubercular mammitis, I have noticed the great preponderance of the affection in one or other of the posterior quarters of the udder, and thought it might be interesting to others if I recorded the observations of 50 consecutive cases. These were cases, both in town and country, proved by the biological test to be affected.

MONSTROSITY.

I was much interested in Mr. H. Thompson's case reported in your issue of August 19th, and he is to be congratulated on its very satisfactory conclusion. In the case which gives rise to these notes I was not so fortunate.

My patient was a medium sized two-year-old Ayrshire heifer in calf for the first time to a short-horn bull.

When I arrived I found that the owners had been at work for six hours, and all they had to show for it was the hindquarters of a heifer calf which they had cut off at the sacrum with a saw. Naturally the heifer was very much exhausted—practically in a state of collapse—and from the first I had little hope of saving her life. However, after administering a stimulant, I proceeded to make an exploration, but it was some time before I could even partially make out the state of affairs. After a little, I made out distinctly the now truncated body of one calf and the hindquarters of another, also, that there was no abdominal wall, the viscera floating about in the uterus. The diaphragm was intact, and then I found there was only one thoracic cavity. Two fore limbs were also within reach, but I was unable at that time to touch a head.

I need not detail my mode of procedure, suffice it to say that after several hours work, during which I removed everything within reach likely to take up room, of which there was little enough, I was quite unable to divide the calves. With the mass drawn within suitable distance, it was impossible to work, and *vice versa*, with room to work I could not reach the foetus.

Tuberculosis of the udder is usually defined as being a chronic mastitis, usually of one quarter, preferably a hind one, characterised by progressive induration and hypertrophy, and unaccompanied by heat or tenderness of the organ.

I have been surprised on occasions by the rapid course of the disease; an udder apparently normal at one visit, being found on second visit a month later to be markedly hypertrophied and indurated. Other cases again are not marked by any great hypertrophy but the induration is steadily progressive.

The owners were by this time "anxious to see the freak," to use their own words, and suggested slaughtering the heifer. Her chance of pulling through, even though the foetus had been removed, was practically *nil*, so she was killed, and I was then able to make an examination of the monster.

The thoracic cavity was formed by the sternum of each calf being divided mesially, and each half, instead of joining its fellow, was united to the opposing half of the other sternum. That is to say, the right half of sternum A was united to the left half of sternum B, or *vice versa*. A transverse section of the thorax was thus more or less rhomboidal in shape. The single heart was apparently normal in shape and structure, but somewhat larger than usual. There were two lungs of normal shape and size.

An accurate study of the abdominal viscera was difficult owing to the treatment. There was only one rumen, reticulum, omasum and abomasum, but where the bowel bifurcated to reach the anus of each calf could not be ascertained. The liver was very large, in fact it looked like two joined together. There was on the left side a small extra lobe exactly like the Spigelian lobe of the right side. There was only one spleen, but there were four kidneys.

Monsters of course are not rare, and my excuse for detailing this case at some length must be its rather unusual form.

In an article in *Le Journal de l'anatomie et de la Physiologie Normales et Pathologiques de l'homme et des Animaux*, July—August, 1906, M.M. Lesbre and Forgeot describe several cases of monstrosities in children which resemble this case so far as the formation of the thorax is concerned, but differ

from it in that the posterior extremities are not duplicated.

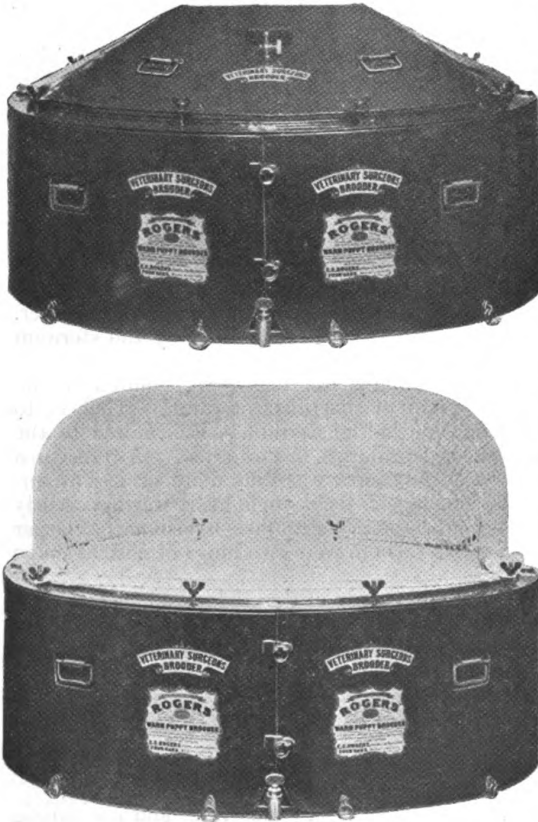

In describing the contents of the thorax, M.M. Lesbre and Forgeot state there are sometimes two hearts, which may be enclosed in the same pericardium, or the heart may be single, but by reason of its complicity, indicating double origin. As for the lungs, these are usually four in number, but the two innermost are more or less atrophied, and sometimes almost non-existent.

On that particular day I had not read this article, so possibly I overlooked atrophied lungs, but the heart certainly showed no signs of being complex, nor was it so large as might reasonably have been expected.

ALEC McTURK, M.R.C.V.S.

Swaffham.

A USEFUL APPARATUS.

The enclosed photos show a novel apparatus that I have found extremely useful in veterinary practice. It is known as a "Veterinary Brooder," not perhaps a very descriptive name, but as it originated from a "Puppy Brooder" invented by Mr. Roger, of Birmingham, the name has stuck to it.

The "brooder" consists of an oval chamber having an inside measurement of 36 inches x 24

inches and 12 inches deep. It has double walls which are filled with hot water, and being padded with thick felt keeps warm from ten to twelve hours. A high wire guard is fitted to the top to keep the patient safe.

I have found the "brooder" invaluable in cases of severe illness, such as gastritis, where the body temperature is subnormal, and after severe operations, as it restores the body heat far more effectively than hot bottles or warm blankets. Another great advantage is the wire guard, which enables me to leave the patient for some hours at a time without fear of the animal becoming chilled.

As will be seen by the second photograph, by fitting a top, which is supplied, the "brooder" can be converted into a very convenient lethal chamber, and I can vouch for its efficiency, having destroyed the largest dog that ever came into my surgery in 3½ to 4 minutes without a struggle, coal gas being used.

The apparatus is made and supplied by Mr. Rogers, of Four Oaks, Birmingham, who has spent much time and money in bringing the "veterinary brooder" to the finely finished state in which he now turns it out.

J. STEWART WOOD, M.R.C.V.S.

Parkestone, Dorset.

ABSTRACTS FROM FOREIGN JOURNALS.

CUTANEOUS SECONDARY MELANO-SARCOMATOSIS IN A DOG.

It is known that the secondary localisations of malignant tumours are especially glandular or visceral in their situation, and only very exceptionally cutaneous. Melanotic sarcomata sometimes form these exceptions. Moreover, the cutaneous localisation of melano-sarcomatosis may be compatible with a long survival of the subject; but sooner or later cachexia and mortal visceral metastases are produced. Ball and Cuny (*Journal de Méd. Vét. et de Zootechnie de Lyon*) relate a case illustrating this condition.

The subject was a seven-year-old dog, which presented, in the region of the internal phalanges of the left fore foot, a tumour of a black colour, of the size of a small walnut, of irregular shape, elongated transversally, firm in consistence, and ulcerated at one point of its surface. The owner had noticed the presence of this tumour six months at least before bringing the dog for examination.

A number of secondary melanotic nodules were found upon the skin upon the whole surface of the body (except the head), but principally about the flanks, limbs, and tail. The nodules had multiplied gradually. They were rounded, hemispherical or lenticular, flattened, smooth upon their surfaces, the colour of Indian ink, and ranged from the size of a lentil to that of a nut.

Upon the posterior limbs, the metastatic nodules were chiefly grouped upon the anterior portion from the femoro-tibial joint to the metatarses. Upon

the anterior limbs, they were found especially on the dorsal aspect. On the inferior aspect of the tail, a series of small nodules were found arranged in an almost straight line.

There was no indication of either glandular or visceral metastases.

Histological examination of the primary tumour showed it to be a round-celled melano-sarcoma. It comprised a rather well developed connective tissue framework lodging numerous rounded, polyhedral, or globular melanotic cells. But, as is often observed in leuco-sarcomas or ordinary sarcomas, certain parts of the tissue were composed of fusiform or stellate melanotic net-work. The melanotic infiltration of the sarcomatous cells was not of the same intensity throughout the tumour, but unequal, varying in different portions of the preparation.—(*Annales de Méd. Vét.*)

MELANOSIS IN ADULT CATTLE.

According to Ostertag, bovine melanosis is usually congenital, and seems to disappear with age. Beel (*Zeitschr. f. Fleisch-u Milch Hygiene*) states that he has often found melanosis in calves, and the following observation by him seems to support the view of the ulterior disappearance of the pigmentary deposits.

A cow of two and a half years showed lesions of the lung, liver, meninges, spinal cord, etc., which are usual in calves, but with this difference—that these organs did not show the characteristic black tint, but were dark-brown in colour. All the long bones showed, upon their sectioned surfaces, a dark-brown colouration which was especially pronounced at the exterior, but diminished gradually as the more internal portion of the bone was reached.

This case certainly seems to confirm the view that the melanotic deposits retrogress with the advance of age. Nevertheless, typical and well-marked lesions may persist in adult animals, as the following observation by Beel testifies,

A cow of five years old showed deep black deposits in the periosteum of the inferior maxilla, the connective tissue of the parotid gland and of its excretory duct, the aponeuroses of the internal masticatory muscles, the retropharyngeal glands, the palate and soft palate (where the deposits were in starry spots), the tracheal mucous membrane, the first fifteen cartilaginous rings of the trachea, the lung, the liver, and the dura-mater (which was absolutely black). The renal calyx presented some spots; and a single small irregular deposit was upon the heart. The connective tissue of the coccygeal muscles was deep black, while the remainder of the muscles were free from lesions, as were also the spinal meninges.—(*Annales de Méd. Vét.*)

THE EMPLOYMENT OF CHLORAL IN THE TREATMENT OF EVERSION OF THE BOVINE UTERUS.

Knoll describes (*Tydschrift voor Vecartsenijkunde*), the treatment he adopts when called to a case of eversion of the uterus in a cow. He commences by administering from 35 to 40 grammes of chloral in

a lukewarm draught of decoction of linseed. Narcosis quickly follows, and is generally obtained during the time which the practitioner spends in changing his dress. The cow is then placed in a position strongly inclined from behind forward, which is accomplished by placing two sacks filled with hay under her. Reduction is then effected in the most convenient manner, and a relapse is prevented by the application of a suture. The animal remains in the same position until the narcosis disappears, which speedily takes place.

By this method of procedure Knoll has never lost a cow affected with uterine eversion. He has never observed any untoward results from the employment of the chloral, though he admits that, in the event of slaughter becoming necessary, it may communicate an odour to the meat. He employs the dose of 35 grammes in preference to the larger one of 40 grammes. He has also used chloral with good results in cases of excessive straining after parturition.—(*Annales de Méd. Vét.*)

W. R. C.

THE NATAL VETERINARY MEDICAL ASSOCIATION.

The second annual general meeting was held in the office of the Principal Veterinary Surgeon, Maritzburg, on Friday, June 30. The following members were present: Messrs. H. Watkins-Pitchford, President, in the chair; W. M. Power, Vice-President; F. J. Carless, S. B. Woollatt, C. M. Sharpe, C. H. Cordy, J. B. Collyer, F. Hutchinson, and A. W. Shilston, Hon. Secretary.

Visitors: Capt. McKenzie, A.V.C., Mooi River, and Mr. F. A. Verney, A.V.S., Basutoland.

The minutes of the last meeting were read and confirmed.

A letter of apology for non-attendance from Mr. Amos, Durban, was read.

CORRESPONDENCE.

The SECRETARY read the correspondence which had taken place with the Cape of Good Hope and Transvaal Societies relative to the South African Veterinary Surgeons Bill and the proposed Federation of Veterinary Associations.

A discussion on the question of Federation followed, and a resolution was passed in favour of the scheme proposed by the Transvaal Society.

ELECTION OF OFFICERS.

The following officers were unanimously elected for the ensuing year:

President.—Mr. H. Watkins-Pitchford, F.R.C.V.S.

Vice-President.—Mr. F. J. Carless, M.R.C.V.S.

Hon. Sec. and Treas.—Mr. A. W. Shilston, M.R.C.V.S.

The SECRETARY read the balance sheet for the past year which showed a balance in hand of £15 14s. 3d. This was passed.

The PRESIDENT then demonstrated the method of employing a hæmoglobinometer of his own design; this instrument is very compact, simple in principle and without any special requirements, enables one to quickly and accurately determine the hæmoglobin contents of a patient's blood.

A blood-collecting outfit was also shown; the appliance, which is no larger than a thermometer case,

enables one to make a dilution of blood of known strength which can be kept indefinitely; from this dilution, blood counts and films for microscopical examination may be made at any time.

The Natal Anti-toxic syringe was exhibited and its use explained; the syringe contains one dose of Antivenene, is of convenient size for carrying in the pocket, and in case of snake bite is readily available.

Mr. CARLESS exhibited a number of dental instruments of useful designs. Several specimens of parasites were shown by the Secretary.

The appliance for testing the Arsenical strength of dipping fluids, patented by Dr. Pitchford, was exhibited and the method of using it demonstrated with dips of various strengths.

The meeting closed with a vote of thanks to the President.

A. W. SHILSTON, Hon. Sec.

Foot-and-Mouth—West Hallam Outbreak.

In the present outbreak at West Hallam, Derbyshire, the disease was of a mild character, and presented the following symptoms: The earliest indication of anything being amiss with the stock was revealed to the owner on Friday, the 18th Aug., in one of the cows slaving abnormally at the mouth, and a similar condition in another cow on the following day. On my arrival at the farm, on the forenoon of Sunday, the 20th Aug. I found three dairy cows affected, all in different stages of the disease, and as I had the opportunity of examining

these and other two cases later developed, the following report may be of interest to owners of stock.

The earliest clinical symptoms were smacking of the lips, a profuse flow of saliva from the mouth, a watery discharge from the eyes and nose, which ultimately became thicker in consistency, an abnormal pink hue of the lining of the mouth—the roof of the mouth was covered with petechial (blood) spots. Careful examination of the toothless border of the upper jaw as well as of the tip of the tongue revealed the characteristic vesicles (bladder, bleb, or blister) seen in this disease. These were filled with a clear fluid and were more oblong than oval in shape. The temperature at this stage varied in the different animals affected from 103° F. to 104° F. The animals were dull, went off their feed and the bowels were constipated.

In twenty-four hours from the first clinical symptoms the disease was fully developed, and in forty-eight hours the skin over the vesicles shrivelled up, became pale in colour, and on the third day was detached, leaving behind watery erosions, which healed very quickly, and were recognisable by the sharply-marked limits between the sound tissue and the eroded areas which result from the bursting of the vesicles. Within the same period the inflamed appearance of the mouth passed off, the temperature fell to normal and the animals again commenced to ruminate and take food.

In one case vesicles were found on the feet between the digits (toes) which ran a similar course to those in the mouth. This animal was stiff in the act of rising, but could not be said to go lame. (From a column on Foot-and-Mouth disease, by Alex. Levie, F.R.C.V.S. in the *Derby Daily Express*).

* As Diseased or Exposed to Infection

The Royal Agricultural Society and Tuberculosis.

The Royal Agricultural Society has just issued a booklet of 19 pages, entitled "Tuberculosis as regards Heredity in Causation and Elimination from Infected Herds." Practically the work is a long article upon this important subject, written by no less an authority than Sir John M'Fadyen. The booklet is published for the Society by Mr. John Murray, 50a Albermarle Street, W., and its price is 1/-. Members of the R.A.S. may obtain copies at half price by applying to the office at 16 Bedford Square, W.C.

This small work will probably exercise a wide educative influence, from its excellent popular presentation of the subject. It is divided into two parts of nearly equal length, the first dealing with the question of heredity. In this the genesis of the old belief in the importance of heredity in tuberculosis is first explained; and the difference between congenital tuberculosis and an hereditary predisposition to the disease is clearly laid down. The frequency of the former is indicated, and the evidence for and against the latter weighed; and the relative unimportance of both in the causation of tuberculosis in comparison with the far more potent causal factor of contagion is well brought out.

This leads up to the second part of the booklet, which is concerned with the eradication of tuberculosis from a herd. It consists of a careful exposition of the principles underlying an attempt to transform an infected into a tubercle-free herd and the details of their application, full consideration being given to the varying circumstances of the individual case. The various difficulties and discouragements attending such an attempt are not minimised, but, with their causes, are fully explained. No details are given regarding the technique and reading of the tuberculin test, it being apparently tacitly assumed that this will be entrusted to professional hands. Directions as to the intervals between the successive testings and re-testings are given, as also are full explanations of certain well-known apparent failures of the tuberculin test.

In conclusion, reference is made to the economic aspect of the question for the individual owner; and here it is fully admitted that, for the average British farmer, the task of eliminating tuberculosis from a herd is far from easy and is often costly, while the prospect of immediate financial advantage from it does not appear great at present. It is pointed out, however, that the conditions are different in the case of valuable pedigree herds, in which the expense attached to the attempt at eradicating the disease is usually less, while the prospect of obtaining a speedy financial return is greater. A single concluding sentence indicates the obligation upon pedigree owners to lead the way in the campaign against bovine tuberculosis.

The official source and the authorship of the booklet alike ensure it a wide reading, which its perusal convinces us is more than deserved. We doubt whether any work of so small a size has ever been published which is so valuable to the agriculturist. Of course it contains nothing of direct value to the veterinary surgeon, but even to him it may prove of very considerable indirect utility. A veterinary surgeon undertaking the eradication of tuberculosis from an infected herd cannot do better than direct his client's attention to this booklet as a comprehensible exposition of the principles of the operation.

Preservation of Tr. Iodine.

The addition of a small quantity of Calcium carbonate to Tincture of Iodine prevents the formation of iodic acid and preserves the tincture at a very small cost.
—*La Clin. Vet.*

Prosecution of a Veterinary Surgeon.

Mr. William Watt, M.R.C.V.S., 17—21 Lillie Road, Fulham, was the defendant in a summons issued against him by the Royal Society for the Prevention of Cruelty to Animals charging him with aiding and abetting two men, Frank Pearson and George Garner, employed by a firm of coal merchants, in ill-treating a horse used for drawing a coal wagon.

Mr. Bevan, K.C. prosecuted, while Mr. Pheasant solicitor, appeared for the defendants.

In explaining the circumstances counsel said the animal was found to be in a most deplorable condition. There was at the point of the hip an open wound communicating with a sinus some eighteen inches long from which pus flowed freely. A *post-mortem* examination showed that the pus had soaked into the muscular tissues, which had become decomposed and rotten. Mr. Watt told the officer that if the Society wanted a fight they could have one. Counsel commented on the responsibility of Mr. Watt in this matter. He had chosen to take on himself the responsibility of sending out the horse. It was not a case of mistaking the character of a particular disease. Mr. Watt had assumed the responsibility for the working of the horse. A case on somewhat similar grounds went to the Divisional Court, but it was dismissed, against the veterinary surgeon on a technicality. The Court declined to convict because of the form of the summons which was for knowingly counselling the owner to work the animal, instead of with having caused it to be worked.

Rupert Gildersleve, the Society's inspector who stopped the animal, said—the horse was very lame on the off hind leg. Matter was running down the limb and a loin cloth was placed so as to cover the wound. The wound was a few inches below the angle of the hip. The loin cloth was covered with matter. The horse was not perspiring.

Mr. Pheasant: Do you wish the Court to understand that the horse was sent out in the state you describe?—It was in that condition when I saw it. Two veterinary surgeons (Messrs. Case and Piesse) were called to see the horse—one the same day, the other a few days later.

So there was some doubt about the condition?—I don't know about that.

Can you explain why no process was taken before July 15th, although you allege the offence was committed on June 21st?—That is a matter for the head office.

Mr. Bevan explained that the delay was due to the fact that in such special cases as this no prosecution is instituted until the facts have been laid before the Committee of the Society.

Mr. Alexander Piesse, M.R.C.V.S., Brixton Road, said he examined the horse on July 28 at the request of the Society. He described the nature of the wound on the point of the hip, and said the animal went lame on the off hind limb. As he pressed the parts pus came out of the wound.

Mr. Bevan: How did it come out?—In a thick stream proving that there was present a large accumulation of pus. There was an overshot fetlock, and the ligaments were thickened.

How long do you think the horse had been suffering?—Not less than three months, may be longer.

Was it fit to be put in a cart?—No.

In cross-examination witness said a little gentle movement of the horse would cause the pus to ooze out of the wound and so decrease the amount. By a gentle movement he meant a walk round the yard. The pus would have to travel 12 inches before it reached the mouth of the wound.

Mr. Pheasant: A sinus twelve inches long is not exceptional?—Yes, it is exceptional. The sinus had been

in existence a considerable time. Had an operation been performed it would have entailed considerable expenditure.

A horse sensitive to the touch as you say this one was is not necessarily evidence of pain?—No.

Mr. de Grey: What if it flinched?—If it flinched out of the ordinary then it would indicate pain. I can always tell whether an animal flinches in pain or in nervousness. I cannot imagine any one working the animal in the state I saw it. Witness added that a diseased bone could only be discovered superficially by the smell. He found no evidence of it externally. So long as the pus remained there must be pain.

Mr. Bevan: You would not call gentle exercise to place the horse between the shafts of a coal wagon?—Oh, no.

Arthur Case, a veterinary surgeon, of 706 Fulham Road, said that on June 21 he examined the mare at Messrs. Usher's stables and found her lame on the off hind limb. There was a wound on the thigh about two or three inches below the point of the hip. The wound was discharging pus. The muscles of the part were very much wasted. The fetlock joint was very much enlarged and overshot. On manipulating the part in the region of the wound he found the animal suffered pain, and it was not fit to be worked. The wasting had been going on for some time, and the mare had been trying to rest the part as much as possible. The wound was of some months' standing. On July 4 the owners had the mare slaughtered, and witness subsequently made a post-mortem examination. The flesh was very decomposed with pus, and the hip bone tissues were diseased and had been in that condition for some time, a matter of months. The horse could not have been worked without pain.

Mr. Pheasant: Could you not come to any conclusion that there was diseased bone there without cutting the parts open?—No.

Would you form any opinion as to where this matter was coming from without an operation?—You could feel it down the bottom.

Could you tell there was necrotic matter or not in the diseased tissues before the post-mortem?—You could form an opinion.

You don't agree with Mr. Piesse that from external examination no veterinary surgeon could discover it?—I agree with Mr. Piesse.

Mr. Piesse said there was no evidence of a diseased bone. Do you agree with Mr. Piesse there?—Yes. If there had been a diseased bone we should have detected the smell.

Did you really conduct this post-mortem?—The post-mortem had already been conducted.

Mr. De Grey: It was a *post* post-mortem.

Mr. Pheasant: Did you cut up the parts?—No.

Did you find any of the parts missing?—No. I examined the hip bone. The end of it had been cut off.

Will you swear the bone was intact?—Yes. It was divided in two.

Mr. De Grey: How could it be intact if it was divided in two? If I cut you in two you would not be intact?—No.

Mr. Pheasant: Had it been divided before or after death?—After death.

Are you prepared to swear that?—I am.

Do you suggest that wasted muscles caused pain?—No wasting causes pain unless it reaches a certain stage.

Had this reached the stage when the wasting would have caused pain?—I should say not.

Do you suggest that the enlarged fetlock joint is necessarily evidence of pain?—It might and might not be.

Do you suggest the horse resting his leg was evidence of

pain?—No. The accumulation of pus would in itself cause pain on pressure.

And the more the pus was removed the less pressure and less pain there would be?—Yes.

The using of the limb would help to discharge or dispose of the pus from the sinus?—Yes.

Mr. De Grey: Using it at any kind of work?—No, gentle walking exercises.

Why not in a van?—Because the van would cause too much strain on the healthy part. Pain would also come from where the matter had collected, pressing on that particular part.

Would it be like a festered finger in a human being?—Yes.

Mr. Pheasant: Where were the thickened ligaments?—On the fetlock joint.

Was there pain there?—Yes. It was painful to the touch.

Do you know as a matter of fact that while this mare was standing in the stables by your directions the pus accumulated to a very great extent?—Yes.

The question of exercising is a matter which veterinary surgeons differ as to what kind of exercising should be done?—Sometimes.

I take it this mare was not in such a terrible state that you could not understand anyone sending her out?—No.

In reply to Mr. Bevan witness said the muscles and tissues of the hip bone were discoloured and blackened. Disease of the bone was not the same as diseased muscular tissues. There was no diseased bone in this case.

This was the case for the prosecution.

Addressing Mr. De Grey, Mr. Pheasant said an exceptional step had been taken in this case by the summoning of a veterinary surgeon, for aiding and abetting the other defendants. According to law he could not be guilty of cruelty by giving an error of judgment.

Mr. De Grey: The veterinary surgeon gave certain advice in this case. If he did that *bona fide*, that is to say having the means of forming the right judgment and honestly forming that right judgment according to the best of his ability and skill, and if he can convince me that that was so, of course he goes free. I did not see the horse, but it seems to me that no one ought to have worked the horse in the state it was.

Mr. Pheasant went on to say that the prosecution had exaggerated the case. If the animal had been in the state as had been described no one would have taken the risk of sending it out on the streets.

Mr. De Grey: Hundreds of animals in a bad state are worked on the street on the off chance that they will not be spotted.

Mr. Pheasant added that his defence was that so far as the veterinary surgeons were concerned it was purely a matter of opinion. The mere fact of there being a small wound which was discharging pus was not in itself an actual sign of pain to the animal. If a veterinary surgeon was to be prosecuted for saying a horse with pus and no pain could be worked, then a doctor should be prosecuted for sending a child to school with a boil on the back of its neck.

Some questions arose as to the time which expired from the date of the offence June 25th to the date of the summonses July 15th.

Mr. Sidney Polhill, solicitor to the Society, explained that the delay was caused by the fact that whenever a veterinary surgeon was reported for a summons the matter was carefully considered by the Council before proceedings were taken.

Garner, the carman, said he had used the horse about six or seven months. While driving it he had frequently passed R.S.P.C.A. inspectors. There had frequently been a discharge from the off hip. He had never seen any signs of lameness.

Cross-examined, witness said the horse was drawing a ton of coal when he was stopped by the Society's inspector. He washed the off hind limb every morning. Mr. Watt ordered him to put vaseline on the wound. Witness did not put a loin cloth on the horse to hide the wound and prevent anyone stopping him. Mr. Watt saw the animal frequently. Three days after he commenced to drive the horse he asked Mr. Watt if it was fit to work and he replied "Yes, but very lightly." He grumbled about it to his mates. It was an unthankful job to wash off the matter every morning. The wound was about as big as a pin-head.

Robert Joseph Nicholls, a horse slaughterer in the employment of Harrison and Barber, Garratt Lane, Wandsworth, said he went to Messrs. Usher's yard to slaughter the horse, but instead of doing so he took it away with a line behind his cart. It was as sound as his own horse. An abscess had broken the day before inside the thigh and no matter was seen. Eventually he slaughtered it and found the off-hind hip bone had been broken. It had been joined together with a white fibrous substance.

Mr. Pearson, manager, said his employers had never had any complaint about their horses before. The horse in question had a small place on the off hind hip when they bought it. It discharged matter, and Mr. Watt's attention was called to it. Working the horse seemed to have a good effect upon it. He saw no signs of lameness or he would not have had the horse worked.

Cross-examined, Mr. Pearson said that the wound on the hip got no worse during the time she was under his care. Mr. Watt told him that the wound could not be got rid of without an operation. He did not advise an operation, but told witness to work the animal lightly in that condition. Witness did not know why the horse was not operated upon. He could not say why the loin cloth was used. It did not cover the wound. He did not tell the Society's inspector that "we have protected ourselves by calling in a veterinary surgeon." He said "We have been working it under the veterinary surgeon's orders." To his knowledge Mr. Watt had not treated the wound. Possibly the horse in that condition was not a credit to Messrs. Usher and Co., but as Mr. Watt advised light work he did that. If the wound had got worse he would have sought other advice. The horse was destroyed because Mr. Piesse told him an operation would be an expensive matter, but if he had it done away with it would be cheaper and settle the matter altogether.

In reply to Mr. De Grey, witness said that so far as he could see the horse did not suffer pain by being worked. If he had a sore on his own hip he would follow his medical man's advice even if he suffered some pain by working.

Mr. Watt, giving evidence, said he had been in practice 14 years. He had a contract with Messrs. Usher and Co. to look after their horses. He first saw the horse in question 18 months ago. There was a sinus on the off-hind hip, which discharged. The opening of it was about the size of a probe. About three months later the sinus got closed and caused lameness. He reopened the sinus with a lance and the matter came out. Then he told the carman to keep it clean. A day or two later the horse started work again. The condition of the off-hind quarter did not vary, and the wound did not close up again because of the continual movement of the leg. If the passage had been allowed to close there would have been pain caused by the pressure of the pus. So long as the pus came away freely there was no pain, and working would help to discharge the pus. In his opinion to work the animal was the proper course to adopt. At no time did he see any symptoms of pain or distress. If an operation had been performed it would have been problematic as to whether it would have cured the wound. That was Mr. Piesse's opinion too.

The wasted muscle was affected very little by the movement of the legs, the manipulation of which would not cause pain because there would be no pressure so long as the pus was being ejected from the sinus. The fetlock being overshot was not evidence of pain. If he had had any idea the summonses were going to be issued he would have called in other veterinary surgeons to examine the horse before it had been slaughtered. When the animal stood in the stable it got worse, because the pus accumulated. Vaseline was put on the wound to prevent the discharge sticking to the hair and excoriating the skin.

Cross-examined, witness said it was not necessary to slaughter the horse. The head of the firm did that to save the expense of an operation. He would have been exceeding his duty to have called in another veterinary surgeon's opinion when Mr. Piesse said the horse was not fit to work, and, further, he did not think it was necessary. During the past 18 months the sinus had extended three inches, being about twelve inches in length when it was stopped. The wasting of the muscles was caused by the treatment for the discharging wound six months before it came to Clapham Junction. In his opinion the discharge was caused by a piece of dead tissue which might have come from the broken hip. Some foreign body would cause irritation causing the pus. There was no pain caused by the wasting of the muscles. He had not seen other horses working while suffering from a wound like the one in this case.

Wm. Hunting, F.R.C.V.S., Examiner in Surgery to the Royal College of Veterinary Surgeons, said he had heard the evidence in the case. An overshot joint might be a sign of previous pain, and not evidence of pain in that particular joint. No pain would be caused by the limb being worked in the presence of these wasted muscles. With regard to the sinus the animal would not necessarily be caused pain by working. If it was allowed to remain idle the pus would accumulate and cause pain. To work the horse would relieve it by ejecting the matter from the sinus. In the morning the sinus would be sore. He had experience of a case where a sinus took two years to heal up, and the horse was worked all the time. He operated on the animal unsuccessfully, but it worked without lameness for two or three years after and ultimately healed spontaneously. In his opinion Mr. Watt's advice was good and sound in the present case. He had known many cases where horses worked without pain with open wound.

Cross-examined witness said he was of opinion that the sinus was becoming blocked up on the day it was stopped. It caused the horse to go lame. There must be some inflammation to produce pus.

John Watson Brownless, M.R.C.V.S., Police veterinary surgeon, corroborated the last witness's evidence.

Mr. De Grey said he was at a great disadvantage in not seeing the animal in question, because he could judge better by personal inspection than by any amount of evidence as to whether a horse was suffering pain or not. It was a difficult case. He exonerated Garner, the carman. With regard to Mr. Pearson he had sheltered himself under the advice given by Mr. Watt. He (the Magistrate) had to say whether he was convinced without seeing the animal that it was lame and suffered pain. It would take a good deal to convince him that a horse with a sinus as had been described was not suffering pain when worked. Mr. Hunting had said he had known a case where it was possible, but was it possible in this case? Mr. Pearson said Mr. Watt told him he might work the horse, and added "We have protected ourselves." It was not a nice thing to say. Whether it was said or not he could not say. Mr. Pearson denied that he said it. It was clear that he worked the horse on Mr. Watt's advice, and he thought he was safe. Mr. Watt was uncertain when he saw the horse last. Mr. Pearson said Mr. Watt

went to the yard two or three times a week, but Mr. Watt said he went there about twenty times a year. He was not satisfied that Mr. Pearson was justified in thinking the advice he had, held good for such a long period of time. The horse was undoubtedly lame when the Society's inspector and Mr. Piesse saw it. Mr. Pearson ought to have known it was unfit for work in spite of the advice he had from Mr. Watt. With regard to Mr. Watt there was a great difficulty in his (Magistrate's) way. He had given evidence in a honest and straightforward manner. It was not a pleasant position for him to be in, to be in the service of a firm which employs a number of horses. He had said "I am there to do simply what Messrs. Usher's want me. I am their servant." It did away with his independence, and thereby independence of judgment, which was a very important matter. He might hold that Mr. Watt was not giving his advice independently and straightforwardly. Mr. Hunting had said he knew of another horse in a similar condition had been worked for two years without being any the worse for it. That being so he should say that Mr. Watt gave honest advice. He might have thought it was the right thing. Nevertheless it was difficult to think that a professional man should give such advice. The summons against Garner and Watt would be dismissed, while Pearson would have to pay 40/- or a month.

Ritualism in Surgery.

I should like to say a few words here on what is now euphuistically spoken of as "surgical technique," formerly as wound treatment, particularly with regard to its ritual and its expense. The great principles upon which operative success depends are to-day exactly the same as when Lister first preached the gospel of antiseptics. Absolute cleanliness is the essence of the measures by which he carried those principles into practice. Many as have been the modifications of our operative methods since the early Seventies of last century, it is upon the completeness with which this central idea has been secured that the success of each method depends. It needs but little ceremonial to make and keep us clean either in body or in spirit. Simplicity, sincerity, and steadfastness will suffice in both. The modern tendency to make of a surgical operation a kind of ritualistic function is greatly to be deplored. Harm often results therefrom I am sure. We can be careful without being fastidious, and efficient without becoming hysterical; and elaboration of ceremonial will not condone a want of manipulative dexterity or absence of readiness in emergency. Soap and scalding water are our safest and simplest antiseptics, and if we add spirit to the list, the scruples of the most sensitive of surgeons should be satisfied. [From the Address in Surgery, at Birmingham, by Jordan Lloyd, F.R.C.S.]

Why has Dr. Rutherford resigned?

A correspondent in last issue puts it up to *Canadian Farm* to tell why Canada is losing the services of so valuable an official as Dr. J. G. Rutherford at such a critical time in the live stock industry of this country. If it is a question of salary, or of the United States, as our correspondent points out, trying to secure his services, then those responsible for his going are deserving of very grave censure indeed. We are inclined to the view that the reason for his leaving is not a question of health or of salary, but one of friction in the inner working of the department. The persons responsible for that friction should be removed or put where they can do no harm, and every effort made to retain Dr. Rutherford's services.

The Department of Agriculture loses a particularly capable outfit of brains in Dr. J. G. Rutherford, C.M.G., Veterinary Director-General and Live-Stock Commissioner of Canada, who leaves the Government service for work that will bring him more money and greater peace of mind. Rutherford knew his job up and down, straight through, and clear across. He had been a Member of Parliament and knew what the people wanted. He had been a farmer and knew what the farmers wanted. He was trained as a veterinary surgeon in the thorough English school and knew what the animals wanted. When he took hold in 1902 he found nothing to his hand except an Act of Parliament which was so much waste paper. In nine years he had created a health-of-animals branch, a meat and food inspection service with a hundred inspectors, a biological laboratory with a staff of trained pathologists, and a live-stock branch that is doing much to promote friendly relations between breeders and their market. Quarantine work has been systematized and the importation of live stock into Canada is now thoroughly under the control of the department. Hog cholera has almost disappeared; glanders has been stamped out except in Saskatchewan; cattle mange, horse mange, sheep scab, and many other minor diseases have been effectively handled. Rutherford brought unusual powers of special investigation to his duties. For example, when an epidemic broke out among the cattle in Nova Scotia he discovered that it was due to a poisonous weed. He brought in sheep that throve on the weed and put an end to the epidemic. As president of the American Veterinary Medical Association, Rutherford had the chief hand in forming the International Commission for the Control of Bovine Tuberculosis, whose good work has just begun. Incidentally Rutherford did a lot of veterinary education by taking it out of private hands and making it a university course. Like many brilliant, original, and public-minded civil servants, he seems to have been too good to keep.—*The Canadian Collier's*.

Seizure of pork.

The Municipal Veterinary Officer of Health, Rheims, ordered the seizure of a carcase of a cryptorchid pig which also showed signs of nephritis. The owner sued for its value on the grounds that cryptorchidism was not harmful to health, and the authorities could not seize on that account.

The plaint was dismissed on the evidence of the strong sexual and uriniferous odour of the flesh.—*La Clin. Vet.*

SMART-BICKLEY.—On Aug. 19th at the Registrar's Office, Dartford, William W. Smart, I.S.O., M.R.C.V.S., "Ypsilanti," Bexley, Kent, to Julia, widow of the late C. C. Bickley.

WOODROW.—Aug. 25, at Onslow House, Swinefleet, Yorkshire, to Mr. and Mr. John S. S. Woodrow, a daughter.

CORRESPONDENCE.

"SIDE-LINES" IN PRACTICE.

Sir,

As one who learned pig spaying as a post graduate and found the general castrating in a country district save writing cheques for petty cash, I endorse your suggestion that in these hard times no castrator but a qualified man should have a chance where the latter resides. The worst of pig cutting is that one is so differently treated when going to a farm for this purpose instead of to visit valuable animals in illness. I am not referring to loss of dignity, which is bad enough, but the invariable waste of time. Farmers and their men will finish a distant job when they hear the whistle or see the castrator's nag in the road; and the sow and pigs have first to be driven home and then to be separated, and oftener than not the little pigs break through the rotten sides of the pound when it is thought that they are at last secured. All this vexatious waste of time and dignity and then the smell of "pig" and the filth about one's clothes, tends to make the established practitioner or the senior partner more willing to endure the vagaries of the pet lady's pet dog than "gather gain by every wile consistently with honour"—plus "gommer."

Turning to another neglected branch of small practice, or a "side-line" as store keepers would call it: how we have neglected our opportunities in the direction of avian pathology! All sorts of men write books on the diseases of poultry and of cage birds, but never a veterinary surgeon: if we except the work of Salmon in America. No veterinary Surgeon was on the Committee of Inquiry on Grouse Disease, whose splendid report is now to hand in two volumes with coloured plates. Instead of leading in such a matter, we are spoon fed out of the dish prepared for laymen, by eminent medical authorities. This voluminous report is simply stuffed with material of interest to any but our most advanced men, and the work should certainly be acquired for the College Library: the cost (two guineas) being too great for those who cannot subscribe one guinea to keep the veterinary flag flying at Red Lion Square.

Elderly graduates of the London school will read with satisfaction that the late Dr. Cobbold was right in attributing the grouse disease to strongylosis and not to *Bacillus coli*, as suggested by Klein. If I might offer an opinion, I should say that the many bacteria one finds in birds are chiefly due to failure of the liver to eliminate toxins produced in the intestines, especially the caeca, where the movements of ingesta are very slow and the ingang and the outgang is the same, and the one function is suspended while the other is performed. The condition of the livers of many birds sent me for examination as to parasites is such as to point to toxæmia—as a result of excessive numbers of thread worms in the caeca, or of tapeworms in the duodenum, or both. These macroscopic parasites may be present in a bird which succumbs to bacterial necrosis of the liver induced by coccidiosis, but I will forbear to speak of subjects about which the new generation of better educated men are so much more informed: my excuse for saying as much is, that I have exceptional opportunities of seeing gallinaceous birds, and many wild specimens, besides caged creatures after death. Let me use what space you may care to grant me, Mr. Editor, in recommending practitioners to take up the subject of avian disease, reading Salmon and a good deal on parasitism in Neumann, and, if they can find what they want in dear old Cobbold, (I confess I never could find anything in that learned man's books, as he adopted a pleasant conversational tone and a discursiveness primarily introduced to render interesting what was then thought very distasteful) and borrow indefinitely the Report on Grouse to which allusion has already been made. Our young men have had the training that will enable them to quickly grasp and assimilate all that is worth having, and then, as the result of their own further observation, give us sound advice to retail to poultry owners. One of the most important matters elucidated by the Commission was the life cycle of the *Trichostrongylus*

pergracilis. May we not suppose that other strongyles develop from the ova passed out on the ground in a few days, become motile embryos, perch upon the plants most likely to be eaten by the normal host, and again become capable of reproduction in something like a fortnight! If the strongyles of colts, and minute worms which play such havoc with sheep pass a certain time upon the ground as soft embryos, may we not hold out hopes to our much tried clients that, by heavy manuring with salt (and other worm killers with higher manurial value) the plague of strongylosis may be overcome. If we except the ravages of tapeworm in lambs, it may be said that strongyles are the greatest source of loss by way of parasitism that farmers and poultrymen suffer.

OLD ORADIAH.

THE PHYSIOLOGY AND PATHOLOGY OF RUMINANTS.

Sir,

The various articles and discussions on this subject that have appeared in the last few numbers of *The Veterinary Record* are interesting and instructive; they go to show that finality has not yet been reached in this branch of veterinary science.

I therefore venture to express the opinion that still further consideration should be given to the physiology and pathology of the animals of the farm other than the horse, as in the near future the veterinary surgeon will have to pay greater attention to farm animals than he has in the past quarter of a century.

We read in the daily press that the Government are going to grant £50,000 for agricultural research, which is to embrace vegetable and animal physiology and pathology, and hope some of the younger, more ambitious, and talented members of the profession will qualify themselves in order to benefit themselves and the public by this grant; if they fail, probably doctors of science or medical men will get the positions.

Every practitioner in country districts has the opportunity to make observations during the life of his patients and often after its death. But how many devote any time to make them. The last 25 years very little study has been devoted to cattle beyond their contagious diseases; at least our journals are lacking in such observations.

I believe it was a mistake to amalgamate the teaching of pathology and therapeutics of cattle with that of the horse and dog, as was done in this country a few years ago. In many of the Continental schools, notably those in France, the Chair of Cattle Pathology is still kept distinct from that of Equine and Canine Pathology, and with very good results.

But I have gone astray from the path I intended when I took up my pen, and that was to ask Mr. Hoare a few questions, which I hope he will endeavour to answer to the best of his ability.

1. Is the ingesta in the omasum always dry and in leaves, and does the mucous, epithelial, or papillary membrane always peel off easily after destruction of a healthy animal?

2. What is the difference between the condition of the omasum and its contents during health and that of the so-called impaction from disease?

In other words, do veterinary surgeons often make observations after death of a healthy animal and compare the conditions with those found after death in a diseased animal?—Yours truly,

ENQUIRER.

PROFESSIONAL FEES AND THE R.V.C.

Sir,

In the interesting if somewhat abusive correspondence now taking place in your valuable journal, I notice that Mr. F. O. Parsons alludes to the charge of the R.V.C. for the keep and treatment of a dog, which is 5/- per week, or about half or one-third that usually obtained by the majority of practitioners in and around London and other parts.

According to the last report of this institution issued to subscribers I glean that after receiving £1,000 from the Government and £300 from the Royal Agricultural Society the College only just managed to show a small balance, and which goes to indicate that without these two grants the Royal Veterinary College would soon cease to exist. So much for the business side of the College.

As a large taxpayer for my position in life, I have to contribute to this grant obtained from the Government, so I think it is unfair that the College should too keenly compete with me. But on the other hand, the College is largely kept going by the present students, the majority of whom will one day obtain their diplomas, and many of them will then find the ground cut from under their feet by the very institution they assisted, and will have to assist, to keep on its legs.

Is this just or equitable?—Yours faithfully,

HENRY GRAY.

PROFESSIONAL FEES.

Sir,

Having followed the recent correspondence relating to professional (I feel almost inclined to insert, like Mr. Parsons, a note of interrogation here) fees, for attendance on dogs and cats, it has occurred to me to wonder what men belonging to other professions must think of us should they have had the opportunity to pursue *The Record*.

To attempt to arrive at a "reasonable" or "just" fee for "all and sundry" who profess to dabble in this branch of veterinary science appears to me like putting a market value on our services, to the ultimate total extinction of the professional element. As it is this exists unfortunately in name only among many practitioners, while others find it necessary to point it out to would-be clients on a board, the size of which would shame a music-hall advertisement contractor.

Does anyone know of a profession in which the members all charge alike? Do barristers, doctors, dentists, etc. fill up the correspondence columns of their professional journals in bickering over fees? I think not. But probably the more fortunate ones feel, as we should, sorry for those who are forced to accept little fees because they cannot—often for reasons better not inquired into—obtain larger ones. I have known doctors who have to be content with the magnanimous fee of 1/6 for advice and medicine, while others in the same town have no difficulty in obtaining 7/6 or even 10/6; also dental surgeons who cannot ask more than 1/- for extracting a tooth, yet their neighbour's minimum fee is 5/-.

And so with veterinary surgeons, whose fees must always vary with the reputation, capabilities, and personality of the practitioner and with the establishment he keeps.

I have seen so-called infirmaries and boarding-kennels the quintessence of filth and discomfort; the food on which the poor inmates are fed being on a par with the surroundings, and others which, comparatively speaking, are equal in comfort and cleanliness to an ordinary hospital ward.

Your correspondent "Rusticus" would like to know the actual cost per week to the practitioner for keeping a dog or cat. Surely this must depend upon what they are fed on, and in the case of dogs, whose size varies so much, the quantity of food must be taken into consideration. If the animal is ill, in certain cases, to feed it properly expensive foods such as Brand's essence, Valentine's, etc., must be given, and it is quite impossible to buy these when one only charges 5/- per week—four tins of Brand's alone will cost this—hence the animal first has to suffer, the owner next through loss of his or her pet, and ultimately the practitioner through loss of reputation.

I used to know a suburban veterinary practitioner whose unvarying charge for boarding was 3/6 per week for cats and 5/- for dogs (any size), and with treatment 5/- and 7/6 respectively. Now his boarding charges might be considered fair for cats and small dogs in that district, but the additional 1/6 and 2/6 for treatment (including operations—such as they were) would appear at first sight ludicrous, but for the fact that it happened to be the kennel boy who carried out the treatment (the butchery part excepted), and I believe this to be

the case in many instances of cheap practice. It is difficult to understand why veterinary surgeons in good class neighbourhoods do take in dogs and cats at such low figures unless it is for the above reason, viz., that any yard boy or man, however ignorant, can give "sufficient attention" to these animals, in the practitioner's estimation, while he himself devotes his time and brains in attending the larger ones.

Mr. Parsons suggests that "many of us do not know what to charge," should it not be that "many of us do not know *how* to charge" for attendance on dogs and cats? The average V.S. has, for so long a time, been in the habit of treating and obtaining fees for animals whose *commercial value* comes uppermost, that he cannot readily adapt himself to a class of practice in which *sentiment* plays by far the more important part. Personally, I find people will pay as much, and often a great deal more, for attendance on their pets than the average horse-owner will for a horse.

"Rusticus" mentions a "prominent" firm in the West End who, according to one correspondent, charges 4/6 or 5/- per week for keep and treatment of a cat. I do not know this firm, but as I get a considerable number of cases from that wealthy part of London, I hope that this "firm" will not raise its fees, for I have found that cheap practitioners and dogs' homes indirectly contribute largely to my income.—Yours, etc.,

J. McRAE FROST.

Wimbledon, Aug. 28.

Sir,

I am sorry "Rusticus," who tells us he is "a mere rural person," has not a logical mind to put into practice his injunction that this discussion should be conducted civilly and reasonably and not allowed to degenerate into abuse. I advise him to pluck the mote out of his own eye before he performs on mine. He appears to me to have lost his head and become quite fanatical. Probably he is, as his pseudonym suggests, a rustic by origin, and therefore, as his actions show, by spirit. If so, I can forgive him for his attitude—that of a very narrow-minded, unchivalrous, vindictive person, who readily jumps to conclusions, imputes evil motives, and speaks contemptuously of a great number of his *confrères* whom he considers extortioners and inhuman, and unworthy of the confidence reposed in them by their employers. He sneers at a branch of their legitimate work as if it was beneath his notice, but forgets 'Tis a dirty bird that fouls its own nest.

As to the firm, or a member of the firm he champions, how should I know to whom he refers, since there are so many estimable ones in London who, I believe, have done yeoman service to their employers, to the profession and to themselves, and have carried on their infirmaries and practices hygienically, and who generally charge "live and let live" fees commensurate with the skill, care, expense, and attention bestowed on the patients entrusted to their keeping; and the questionable establishments and the condition of their inmates of which he speaks libellously and with pretended great authority I have not yet encountered them. I will, however, say this, that in all those veterinary establishments I have been into the last thirty-five years I have in every instance found the animals to have been kept in a far more sanitary state and fed much better than a great number of people, including unfortunately a few veterinary surgeons, who have been compelled by dire necessity to live in a dingy, dirty, squalid room or surroundings and from hand to mouth, and sometimes scarcely that.

"Rusticus" is so ignorant as to believe his *confrères* are so ignorant as to neglect their own interests by not humanely and hygienically treating their patients. His idea is to level down fees; my object is to raise them up, at least to the level of obscure but nevertheless worthy suburban practitioners, who evidently from report charge more than the firm he so indiscreetly champions and holds up as a model to be imitated by his *confrères* whom he malevolently abuses and libels.

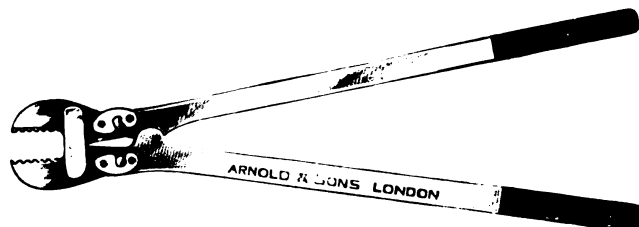

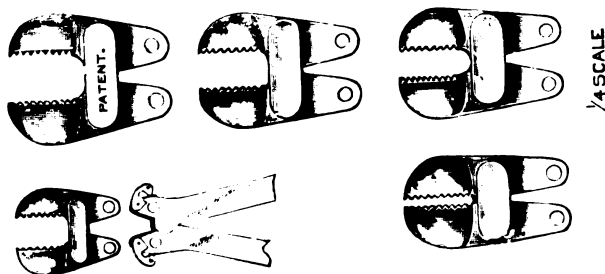

VIS UNITA FORTIOR.

"MAGNUM" PESSARIES.

(HEWLETT'S)

"Magnum" Pessaries are prepared with a medicated non-oily base which is both effective as a Uterine Antiseptic and of special benefit in Parturition both in Cows and Mares.

A "Magnum" Pessary should be inserted directly after parturition in order to maintain the Uterus in a healthy state. It can be inserted with the greatest ease and will keep the parts in a thoroughly antiseptic condition for a lengthy period.

Alkaline "Magnum" Pessaries have recently been recommended to neutralise excessive acidity of Vaginal secretion.

"Magnum" Pessaries are supplied according to various formulæ as below, and Veterinary Surgeons' own formulæ can be made up as required.

		Doz.		Doz.

THE UNIVERSITY OF LIVERPOOL

Veterinary School,

NEXT SESSION COMMENCES SEPTEMBER 28th, 1911.

Diploma of Membership of the Royal College of Veterinary Surgeons.

The Examinations for this Diploma are conducted at the University. Complete courses of instruction are given in the several subjects of these examinations, and are specially designed to meet the requirements of students preparing for the Diploma. Excellent facilities for practical hospital training are afforded in the three large hospitals attached to the School.

The University laboratories are completely equipped, and provide exceptional opportunities for the practical study of the various subjects of the curriculum.

Post-graduate Courses.

Courses in Comparative Pathology, Bacteriology, &c., are specially arranged for officers of the Army Veterinary Department, Colonial Veterinary Surgeons, and others.

D.V.H. Course. This Course taken during the Autumn and Lent terms, qualifies for the examination for the Diploma of the University.

Full particulars as to Preliminary Examinations, &c., together with prospectus, may be obtained on application to—

J. SHARE-JONES,

Secretary to the Board of Veterinary Studies.

THE VETERINARY RECORD

A Weekly Journal for the Profession.

EDITED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1209.

SEPTEMBER 9, 1911.

VOL. XXIV.

T. S. COBBOLD, M.D.

The recently issued monumental final report of the Committee of Inquiry on Grouse Disease will draw some attention to the memory of that sterling worker, Cobbold. Many years ago Cobbold indicated a nematode as the cause of the well-known epidemic grouse disease. This was denied by Klein, who attributed the affection to a colon bacillus. The present Committee, in its exhaustive enquiry, found that Klein had made the error commoner in those days than now, and largely explicable by the circumstances—of mistaking a putrefactive for a pathogenic organism. This point settled, undivided attention was focussed upon Cobbold's theory, and the accumulation of evidence gradually verified it. The *Trychostrongylus pergracilis* (Cobbold) may now be accepted as the cause of epidemic grouse disease, with the proviso that, like many other helminths, it appears to be harmful only when present in excessive numbers.

Cobbold died twenty-five years ago; but the value of his work is only now beginning to be fully appreciated. Every year, however, makes it more apparent. During his lifetime, of course, he was recognised as a great helminthologist—he was one of the few in this country to gain a permanent European reputation in the speciality; but in addition, so far as this country at least is concerned, he was the pioneer of parasitology, constantly pressing its claims to consideration at a time when pathologists in general seemed curiously unable to realise its importance. That time has passed away, and parasitology is now recognised as one of the most important of medical studies. Cobbold, more than any other Englishman of his time, paved the way for that recognition.

So far, the medical and veterinary professions owe a common debt of gratitude to Cobbold. The veterinary profession has additional and special cause to remember him kindly. Many old students of Camden Town still remember the value of his tutorial work on its staff. His strictly scientific work at the School is common property to helminthologists; for much of Cobbold's best original work lay in the veterinary half of his speciality, and a great deal of this was done at Camden Town.

When, a few years ago, a series of boxes at the London School were renovated and inscribed with the names of past veterinary worthies, we regretted that Cobbold's name was not perpetuated. It could easily have been done, and could be yet, by a combination of his old students. He did such yeoman service in a most important branch of comparative medicine that his long and close connection with the veterinary profession should not remain unrecognised.

IMPACTION OF THE OMASUM.

By HUGH BEGG, M.R.C.V.S., Hamilton.

One cannot help admiring the frankness of Mr. Hoare's appeal to his professional brethren for information relative to some of the obscure problems that attach to gastric derangements of the ox.

As the prospective author of a new text-book on Veterinary Medicine, it is gratifying to know that, in the preparation of his volumes Mr. Hoare is not content when he reaches a baffling obstacle simply to plagiarize the books of other authors (home and foreign) or to repeat their plagiarisms, and by mixing a little Irish spice to the old pabulum, hand it over to his readers as original matter. I think his attitude augurs well for what we may expect to find between the covers of his treatise.

No living veterinarian is capable of writing with a master hand on every phase of veterinary medicine, and probably ten men could be found who could write convincingly on equine digestive troubles for every one who would venture to tackle in an original way the similar diseases of bovines.

Before giving my humble opinion on Mr. Hoare's first query: "Does impaction of the omasum occur as a disease *per se*," I would ask: What are we to understand by impaction of the omasum?

I suppose we all believe that the contents of the omasum are always, in health, stored between its leaves in a drier state than are the contents of any other viscus in any of our ordinary patients, but, has any one ever seen the 3rd stomach of the ox distended to two or three times its normal size with dry food?

We often meet with enormous impaction of the rumen in the cow, extreme distention of the stomach of the recently weaned foal with indigestible grass, and every equine practitioner is aware of the extent to which dry impaction of the colon occasionally obtains in the horse, but, though the manyplies may, and does, vary in size, I cannot say I have ever seen it much increased in its dimensions or impacted in the sense that the rumen of the ox, the stomach of the foal or the colon of the horse very often are.

My experience among Ayrshire dairy cows compels me to give an emphatic negative to this query.

Twenty years ago in the district in which I practised 50 per cent. of all the digestive troubles of the milch cow were considered cases of "Fardle bound," and permanent pastures rich in Timothy grass were considered a potent cause of the disease.

Without hesitation I can affirm that scores of dairy cows at that time were sacrificed by stock-

owners and veterinarians alike to the wholesale use of Epsom salts and treacle.

The history of the cases was as follows:—Early symptoms, refusal of food, decrease of milk, general depression and disinclination to move, with perhaps a degree of tenseness of the abdomen, irregular temperature of horns and ears, shallow breathing, expiration sometimes accompanied by a moan or grunt more or less audible, and if present more manifest when recumbent, fæces scanty and it may be constipated, though often normal at first in consistence.

The invariable first dose given was 1lb or more of Epsom salts and 3lb or so of treacle, and, when this was accompanied by the intelligent application of comfortable, well secured clothing, and the medicine, instead of purging quickly and copiously, acted as an aperient, the animal was often well on the way to recovery within 36 hours, normal peristalsis having been restored. But if the saline purge produced forcible and repeated watery evacuations, or, having hung fire, was followed by another, dose producing the impatiently wished-for result and particularly if the cow was inadequately clothed while undergoing the storm and loss of heat that accompanies copious watery evacuations, the latter state of the patient was found to be worse than the first.

The excessive activity of the bowels was followed by a degree of paresis resulting in the absence of fæces for a period. This, or the appearance of a little dry fæces (dry, because it had given up its water during a long and slow travel over an absorbing surface) was, at once alike the clue that the third stomach was blocked, and the excuse for giving another and probably larger dose of physic.

The devotees of this cult have been known to repeat the experiment for seven times before the animal succumbed, and though sad experience might have led them to doubt their tenets—you would find them at the post-mortem, pointing with pride to the third stomach which would turn up firm in consistence every time, and was held to justify (?) their shrewd diagnosis and treatment and illustrate the need for more heroic doses in the next case.

What were the other lesions that were ignored? Simply the toxicological lesions of Epsom salts and treacle, an outraged digestive canal—gastro-enteritis—the chocolate-coloured contents of the abomasum and bowels being plentifully mixed with blood clots, and we have frequently seen a portion of the bowel sauged with blood.

That the omasum was found to be as firm or firmer in consistence than the same organ from a newly killed fat bullock (and we have seen many such that were difficult to pit with the toe of a boot) was but the natural result of its proximity to the intensely inflamed and sensitive abomasum.

The slight red staining of the contents and the free edge of the leaves of the omasum occasionally seen is invariably due to the backwash of the abomasal contents through the somewhat large and patent opening that connects the two compartments.

Many and varied are the diseased conditions which give rise to the common train of symptoms already referred to that were and are still considered pathognomonic of murrain and no hurried examination is sufficient to form a diagnosis and suggest proper treatment for the oppressed cow with a grunt. We have to be painstaking and deliberate in making deductions, if we would avoid the pitfalls of improper treatment, and particularly the blind use of purgatives.

The patients most commonly martyred by the action of purgative medicine have been those suffering from

1. Pleurisy affecting those parts of the pleura that are difficult or impossible to examine by auscultation.

2. Traumatic pericarditis in the early stage before hydrops pericardii has begun.

3. The presence of a foreign body at any part of its transit from the thorax into the second stomach.

4. Hepatitis, hepatic abscesses, etc.

5. Peritonitis, local or generalised.

I am convinced that local peritonitis immediately behind the lower third of the diaphragm (non-traumatic) is a very common lesion in thin milch cows. Witness the large number of carcasses of old cows that exhibit the lesions of peritonitis (apparently non-tubercular) at this site.

The complaint is commonly met with at those seasons when the nights are chilly and wet, or frosty, and the dairy cows are out in the fields.

I am of opinion that senile animals deficient in fat contract peritonitis by a simple and complete chilling of the abdominal wall and the surface of the adjacent organs through prolonged contact with the cold earth. This happens all the more readily if the cow has been heated on the way to the field, and being tired she spends more time than usual in the recumbent position.

6. Congestion or inflammation of the abomasum.

7. The early stage of serious disturbance in the pregnant womb.

THE ETIOLOGY OF GASTRITIS.

I feel sure that the great majority of the cases of abomasitis which I have encountered before and verified by examination after death, have been directly caused or aggravated by the inordinate use of purgative medicine.

But we have often met with cases of a typhoid nature caused by ptomaine poisoning from the use of decomposing roots, in which the symptoms were sudden and grave, accompanied by high fever, and occasionally cerebral disturbance, the animal collapsing in two or three days.

In such cases the most constant visceral lesion revealed on post-mortem examination is gastritis, with hæmorrhages in the intestinal mucous membrane.

Again, it has been my experience that next to the peritoneum the sensitive abomasum is more liable to vascular changes from a serious chill than any other abdominal organ, and, under the influence and predisposition of certain digestive derangements—simple in themselves—abomasitis does

readily take precedence of peritonitis when the system has sustained a shock from undue exposure.

Further, we know that cows feed so grossly when free in the fields that they very often swallow acrid and poisonous vegetable, and even mineral substances, to which they have access, and though the rougher particles are so policed by the other compartments that they do not readily reach the abomasum, irritant solutions and juices soon reach the delicate mucous membrane of the true digestive stomach and kindle a fire there.

Sad experience has also led me rightly or wrongly to suspect that a sudden departure from a well balanced food to one on which the nitrogenous ratio is greatly increased, has been on several occasions the immediate or exciting cause of a series of fatalities in dairy herds.

Three years ago, in a herd of thirty dairy cows, the supply of turnips gave out, and because an order for bran had failed to arrive, the owner, to keep up the milk supply, increased the amount of soya meal from 4 to 8 lbs. per head. On the 3rd day three cows became seriously ill, I was called in and though the feeding was at once changed, other four cows sickened.

In five of the cases the illness was ushered in with violent rigors, the thermometer registering from four to five degrees of fever, complete suppression of milk secretion, diarrhoea bordering on dysentery, occasional colicky pains, restlessness and great depression. Each of these animals succumbed within three days, and the post-mortem lesions simulated those of a septicæmia, abomasitis being constantly present.

Smears made from ear blood were entirely negative, while those made from the lesions soon after death, revealed the ordinary putrefactive anaerobes that abound in the blood of a decomposing carcase.

The illness of the other two cows was epileptiform, one made a fair recovery and the other had to be destroyed on account of traumatic pneumonia.

For obvious reasons, everything humanly possible was done to solve the mysterious etiology of this outbreak, but the investigations of the chemist and the bacteriologist and the kindly help of the Board of Agriculture were alike unavailing.

In the year that the different grades of soya meal were first introduced as substitutes for bean and pea meals, I encountered in various herds similar single cases that baffled treatment, and though suggestive of anthrax, were invariably negative.

Bean straw as a fodder for cows is eminently dangerous, and if given in quantity causes acute gastric derangement with the usual accompanying disturbance of the nerve centres, many of the sleepy, paralytic, almost comatose patients becoming absolutely mad before death.

Finally, trouble in the abomasum is always to be expected and anticipated when an animal has swallowed a quantity of material that is known to be poisonously irritant.

In question (3) Mr. Hoare asks how, in a case of impaction of the rumen, the material is disposed of under the influence of purgatives, and he concludes

by saying that if the medicine enters the rumen and reticulum first, it is not easy to explain how beneficial results are produced.

I am not sure that it would be fair to conclude that he is inclined to believe, as many do, that the contents of the rumen and reticulum never reach the abomasum etc. except *via* the mouth through the act of rumination.

That this is true of the grosser particles goes without saying, but it would be difficult to convince me that no liquids emerge from these compartments and reach the true digestive apparatus while the food is being churned and macerated by the powerful walls of the rumen. If I am wrong, will some one explain the following facts?

Years ago, when the prevention of milk fever appealed to us more than it does in these days of our emancipation by the great Schmidt, my favourite prescription was chiefly composed of 6 or 7 oz. of common salt and about 80 grs. of gamboge. I have repeatedly seen this drench given to a cow due to calve while she was in the act of chewing the cud. The immediate result of this interference was the suspension of rumination. With very few exceptions, the dose produced in six or seven hours copious watery evacuations, in the absence of any resumption of rumination.

Now, if liquid medicine measuring from 1½ to 2 pints enters only the rumen and reticulum, which seems proven, and if no assimilation is possible in these compartments, how are the facts which I have stated to be explained away except by a belief in the direct passage of fluid pabulum from these stomachs to the true digestive apparatus?

Further, I have often seen a considerable reduction in the size of an enlarged and firm rumen under the influence of purgative and nerve-stimulating medicine, though meanwhile the animal was never known to ruminate, while the droppings almost invariably contained gross material that had escaped the gauntlet of digestion.

I conclude that in those cases which die the "atony" of the ruminal walls has been so complete that we have failed to establish either the upward act of rumination or the onward movement of fluid pabulum to which I have referred. And I am of opinion that while the specific and more manifest action of these hydragogue purgatives is predilected to the true digestive organs, the medicine very often exerts an accelerating effect on the walls of the rumen through the vagus nerve which is the augmentor of that organ.

In question (4) Mr. Hoare says he has failed to find in all the text-books the slightest reference to "spewing of the cud."

I don't often consult Gresswell except in my lighter moods, but if Mr. Hoare looks up that author's "Diseases and Disorders of the Ox," p. 504-5 he will find some remarks on "Dropping of the Cud," and a fairly good illustration of a suffering cow. This author refers to the disorder as "simple indigestion."

I cannot subscribe to this view, as many of the cases I have witnessed were both serious and protracted. I do not know that we need differentiate, except in degree, between the occasional dropping

of portions of the bolus sent up during rumination, and a well established emesis. I take it that both extremes and all intervening degrees of spewing are dependent on somewhat similar though often obscure causes, and the quantity of food lost is small or great in proportion to the excitement of the rumen.

We know that under the influence of certain reflex stimuli, the contractions of the rumen are very great and often repeated. Observe a choking cow with the offending root lodged in the upper portion of the oesophagus. Reflex messages from the seat of choking set the rumen in active motion and repeated, almost rythmical waves of fluid are sent from that organ distending the gullet as far up as the obstruction to a degree far exceeding the dilation that obtains in ordinary deglutition, while a similar nervous phenomenon stimulates the salivary glands to great activity, so that below and above the obstacle is beset with tides of fluid intended to assist in its dislodgment. Even when not distressed in breathing by tympany, the choked cow is always more or less topsy turvy and nauseated, not from pain suffered in the gullet, but owing to the restless state of the rumen and its contents—an involuntary state of affairs.

Some of the most miserable and repulsive patients I have attended, were those cases of chronic emesis and cud-dropping, which suffered according as they ate, were happiest when hungry, and which revealed on post-mortem diseased conditions of the oesophagus itself or malignant growths involving or unduly pressing on some part of that organ.

That the seat of origin of the reflex act may, in many cases, be elsewhere than in the oesophagus I am convinced, but when Emesis is due to the baneful effects in the stomach of diseased, poisonous, or irritant indigestible food, it is usually sudden, complete and salutary.

The prognosis can never be favourable when "dropping of the cud," at first but little marked, gradually increases over a period of weeks, while the animal rapidly loses flesh, but I have known one such case make a sudden and unexpected recovery as if the bursting of an abscess had terminated the cause of disturbance.

Then we have occasionally seen a cow in perfect health when quietly chewing the cud throw up, for once only, such a mouthful that the buccal cavity could not retain it, and the liquid portion was sent awash over her lips to the ground while the animal, unheeding, continued perfect rumination, delivering upwards of sixty cuts to each bolus.

Beyond saying that this was due to some erratic stimulus to the rumen, need we theorize further? As well might we try to explain the conditions that cause a man, in due sobriety, to bite his own tongue when masticating his food.

We have also to recollect that cows occasionally "quid" food, as the horse does, when suffering from pain during mastication. Though "caries of the molar teeth" is a very uncommon condition in the ox, we occasionally meet with cases in which the teeth loosen and fall out owing to malignant disease of the alveoli. Such cases make a bad job

of chewing either food or the cud, and the animal that has had the misfortune to wedge an unyielding foreign substance between her teeth and the cheek is in similar predicament. Certain "actinomycotic" conditions of the buccal cavity are also accompanied by quidding.

A CASE OF SUB-LUMBAR ABSCESS.

On Thursday, August 24th, I was shown a grey horse lying in a stable on its right side. It was said to be unable to rise, and when encouraged to do so made no effort to use the hind extremities. I was told that when it first lay down it kicked and struggled for some time, but offered no assistance to men's attempts to help it up.

My attention was drawn to two small round openings on the under surface of the tail—one quite on the firm part of the tail, the other close to the softer perineal tissues. A probe suggested they were superficial abscesses, but as one gave exit to a lot of thick creamy pus when pressed, I enlarged it and with my finger sought for any sinus. I could find none, so concluded that these were merely superficial abscesses unconnected with the inability to rise.

With the aid of slings we got the horse up and he stood well. The pulse and respirations were soon normal, and he was left eating hay. Temperature not taken.

The history of the case was that the horse had been away on military manoeuvres and had returned very much out of condition. He went away on August 13th and did four days work without attracting any notice. Then an abscess on the root of the tail was discovered. It was opened, and to guard against infection from possible strangles the horse was isolated. He returned to London on August 20th and seemed well. On the 23rd a second abscess burst on the right side of the tail, above the anus. This was about the size of a crown piece. The pus which escaped was thick, white and creamy.

As I have said, I thought the abscesses were only superficial, and did not connect them with the inability of the hind quarters. At 6 p.m. the horse was standing quietly in the slings. At 5 next morning he hung in the slings so limp and powerless that the man in charge let him down. He lay quiet and died in about an hour.

Post-mortem.—The abdominal viscera were removed and showed no disease. The left kidney seemed very large, and it was removed with all its surrounding tissues—psoas muscles, etc. This mass was then cut into, and the kidney found apparently healthy. Behind the kidney and over the psoas muscle was a large abscess, the contents being white and almost caseous—in quantity about a quart. Further examination showed a sinus containing, here and there, similar pus. This sinus ran along the upper surface of the pelvis and was connected with the abscess at the root of the tail.

The lungs were not diseased, and unfortunately the heart was not examined.

The case is not one I am proud of, but I report it for the benefit of others. Possibly had I taken the temperature I might have found it high enough to suggest some septic change.

I am still puzzled as to the immediate cause of death, because the abscess must have been in about the same condition when the horse died as when the first appearance of pus under the tail was discovered.

I ought to add that neither the kidney, the psoas muscles, nor the spine seemed affected. The horse had been submitted to infection of strangles so far as occupying a stable in which cases had occurred before he went on the manœuvres.

W. H.

RADIOTHERAPY.

The few remarks which follow are of a wholly theoretical and speculative nature, one may therefore be pardoned, perhaps, for having adopted a somewhat hypothetical title.

Speculation and pure theory are of course considered directly opposed to practical efficiency by a section of our professional community, and those who hold these views will do well to skip this article. It seems a pity that the question of Theory *versus* Practice should ever have arisen, as they are essentially complementary, and their combination in one individual should be the ideal of professional excellence. It is conceivable that, satiated for the moment with the substantial diet of practical work, one might in a season of leisure allow the intellectual faculties full sway to wander into realms of pure speculation.

The discovery of radio-activity is no new thing, but it is only recently that the indefatigable researches of scientists have brought it into the sphere of practical politics. The nature of Radium, the method of isolating it, and the phenomena by which it is recognised, are widely known now, but for those who have not studied it a few prefatory remarks may be allowed.

Radio-active substances, as their name indicates, are chiefly characterised by the power they possess under certain conditions of emitting Rays for an indefinite period without undergoing appreciable loss of substance. These rays are capable of conducting electricity, and this is the phenomenon which has led to their discovery, and the possibility of isolating the substances that emit them. Many speculations have arisen as to the source of these rays, and it is of course open to everyone to make his own choice, but the most feasible idea, in my humble opinion, is that set forth by Dr. Gustave le Bon in his work on "The Evolution of Matter." He assumes that these rays are composed of matter in a transitional state, arising from the disassociation of atoms. He holds in short that the law of indestructibility of matter is an erroneous law and that the atom is capable of disassociation into the ether "from whence it came."

In the course of this disassociation an immense, almost incalculable, amount of kinetic energy is

liberated, producing a force able to drive the particles in the form of rays through material substances. Radium is not the only substance that has the power of emitting these rays; it is now known that many substances have the same power to a modified extent. Le Bon has shown that during a *chemical reaction* rays are emitted. The practical method of demonstrating the existence of these rays is to place the substance to be tested in such a position that the rays can fall on a charged electroscope. A description of the technical details of the experiments would be tedious and out of place in this brief article.

Should the substance prove radio-active a discharge of the electroscope occurs along the line of emanation. In this way radium is obtained. By an intricate process of re-crystallisation, etc., from an admixture of radio-active substances, a residuum is at last procured with a maximum power of emitting rays conductive of electricity. With these preliminary remarks one may pass to a consideration of the therapeutical possibilities of the utilization of this tremendous liberation of intra-atomic energy, as evidenced by the rays.

The first experiments known to me in Veterinary work have been directed to testing the effect of Radium enclosed in a tube, inserted in the frog for navicular disease, and buried in the tissues for the treatment of tumours.

The experiments as yet have been too few for satisfactory conclusions to be drawn. The theory, in the consideration of which I would crave your indulgence, is based upon the possible influence that radio activity, or liberation of intra-atomic energy, may have in the therapeutic action of certain "specific" drugs. The number of accepted specifics is small, but their existence is undisputed. Potassium iodide in the treatment of actino-mycosis may be taken as a good concrete instance. The action of this drug is inexplicable by any hitherto adduced hypothesis. One speaks vaguely of "double decomposition," but it amounts to nothing as an explanation. May it not be possible that a chemical reaction with certain elements of the diseased tissue of micro-organisms occurs, leading to the liberation of intra-atomic energy and in some obscure way to destruction of the diseased tissue and the micro-organisms simultaneously? This theory would help to explain the enormous effect of such a small dose of the drug. When one considers the dilution that must take place, and the infinitesimal amount of the drug that is eventually determined to the diseased area, it is helpful to remember that a liberation of intra-atomic energy may multiply the power almost indefinitely.

As Gustave le Bon states, the intra-atomic energy contained in such a relatively small compass as an ordinary penny would, if the means were discovered to suddenly liberate it, annihilate the experimenter and level all the buildings in the vicinity to the ground. Without necessarily accepting these calculations, although those of a scientist of European reputation, it is indisputable that the potential energy resulting from disassociation of the atom is almost incomprehensibly great.

It is superfluous to multiply instances of specifics. The single one given is sufficient for the purposes of this theory. The factors necessary before a specific effect can be obtained are, the affinity of a certain drug for certain tissues or micro-organisms, chemical reaction, and the consequent liberation of intra-atomic energy (?) One might dilate much upon this point, but enough has been said to demonstrate a possible explanation of the action of "specifics."

It should not be supposed that it is intended to claim the agency of this factor in the action of drugs generally. Like Mr. Wallis Hoare, I am, on the whole, sceptical as to the alleged utility of the majority of drugs. To my mind the average textbook on therapeutics is a touching illustration of the credulity and simple faith of mankind. It is only with regard to certain drugs of specific action for certain diseases that the possible influence of intra-atomic energy is deserving of consideration. At present the chief physical evidence we have of the liberation of this force is that which takes the form of rays, but it is not, in my opinion, going too far to suppose that it is capable of being manifested by other forms, governed by laws as yet unknown to us. In this way it may play a prominent part in the action of those mysterious substances the organic ferments of nutrition, and nervous and muscular energy, and of other physiological phenomena hitherto inexplicable. The definition of a ferment, a substance causing chemical change without itself undergoing perceptible alteration, bears an analogy to radium that is significant enough to awaken interest in an enquiring mind.

WAKEFIELD RAINEY, Capt. A.V.C.

ABSTRACTS FROM FOREIGN JOURNALS.

ULCEROUS "LEG AND LIP DISEASE" OF SHEEP.

Melvin and Möller (*Revue Vétérinaire*) give an account of this disease. It has been studied successively by Gilruth, who called it Eczema of the face; then by Clayton, who discovered its microbial nature; and afterwards by M'Fadyean, Williams, Moussu, Benoist, Cadéac, Leclainche, and Vallée, Knowles, Law, and Wing and Flock, who described the venereal form for the first time.

The lesions may appear upon every part of the body, but the parts covered with wool are least exposed. Traumatism favours the appearance of the disease. Sometimes the affection is benign, and sometimes virulent; and several forms of it have been studied.

One form is localised to the lips and legs. It may be acute, with inflammation, ulceration, and necrosis: the bacillus of necrosis being found in the lesions. On the other hand it may be chronic, with stationary lesions and without tumefactions.

A second serious form—the so-called venereal form—is localised to the prepuce in the male, and in the female to the vulva, which is ulcerated and presents a muco-purulent discharge.

A third form, called "Red Foot," is localised to the feet, and especially to the heels and the interdigital space. The ulcerous lesions extend to the sub-ungual tissue and give rise to an infectious discharge.

A fourth form is observed in lambs and is situated upon the buccal mucous membrane, which shows small ulcers and fungoid elevations of a cheese-like odour.

The disease results from the introduction of the necrosis bacillus into the organism by means of traumatism. The bacillus is widely distributed in nature, but it only penetrates the organism by means of a wound. When established in the organism, it secretes toxins which are necrosing in their action and which may affect every tissue.

The bacillus may affect other species of animals than sheep, causing serious lesions; and prophylaxis should therefore be extended to all species. The infection is spread by litter.

Prophylactic measures should of course be adopted, viz., separation of the affected from the healthy animals, careful examination of animals which have been exposed to the chance of infection, and complete disinfection of the sheds and sheep pens.

The curative treatment is based upon disinfectant lines. The diseased surfaces are cleansed; and the ulcers, in mild cases, are treated with an emollient of cresol 5 parts, sulphur 10 parts, and vaseline 100 parts, and, in serious cases, with more active agents—10 per cent. chloride of zinc or 1 part in 7 of nitric acid. In the venereal form of the affection, the ulcers are cleansed and cauterised, and this is followed by injections of permanganate of potash, 1 in 500. Buccal lesions are washed with a solution of 2 per cent. of potash chlorate, or one of 1 per cent. creolin.

In Germany, a simultaneous internal treatment is also recommended, creosote being given in cod liver oil.—(*Annales de Méd. Vét.*)

[I think that there have been instances of this affection having been mistaken for foot-and-mouth disease.—TRANSL.]

SECONDARY CEREBRAL LOCALISATION OF POLYPI IN THE VAGINA.

Jouglar records (*Revue Vétérinaire*) a case of a spaniel bitch affected with numerous polypi, some pedunculated, in the vagina. These were operated upon by excision and curettage. Ten days later, the operation was to be repeated, when the condition of the animal arrested attention. She was somnolent, showed cutaneous hyperæsthesia, and moved towards the left. The eyes were wild, the pupils dilated, and the retino-papillary reflex suppressed. A digestive auto-intoxication due to obstinate constipation was first suspected; but as the condition persisted despite treatment appropriate to this diagnosis, cerebral metastasis appeared probable.

Post-mortem (it is not stated whether the bitch died or was destroyed) the alimentary tract showed lesions of gastro-duodenitis. The viscera were free from metastases. The polypi in the vagina had

recurred. The left cerebral hemisphere was hyperæmic. A horizontal section of the brain passing above the optic layers revealed a neoplasm situated in front of the corpora quadrigemina and occupying the floor of the lateral ventricle.

The tumour had all the macroscopic characters of a vaginal polypus; it was fibro-lardaceous, vascular, and clearly encroached upon the nervous system. Microscopical examination showed the identity of vaginal tumours and cerebral neoplasm, both of which had the characters of lymphosarcomata.—(*Annales de Méd. Vét.*)

URINE TESTING IN THE DIAGNOSIS OF FOREIGN BODIES IN THE BOVINE RETICULUM.

The diseases due to entrance of a foreign body into the reticulum are accompanied by more or less marked peritonitis, which in most cases determines the appearance of albumen in the urine. This has led Neidinger (*Oesterr. Wochens. für Tierheilk.*) to test the urine in 33 cases, all cows, using the nitric acid reaction. Upon post-mortem examination, the diagnosis was confirmed in 29 cases. In four cases a foreign body was present when albumen had not been found in the urine; but in these cases the section revealed only slight and dry peritonitic lesions upon the reticulum. Neidinger therefore holds that in cases where a foreign body in the reticulum is suspected, testing of the urine is of essential importance as a diagnostic measure.—(*Berliner Tier. Woch.*)

W. R. C.

BRACKEN-POISONING.

In the laboratory report for 1909, reference was made to an affection of cattle which it has been customary to attribute to poisoning by bracken. Feeding experiments were also carried out with large quantities of bracken taken from the pastures where the animals had been grazing. The results of these experiments, however, were negative, and no experimental proof of the bracken being poisonous was obtained. It was also pointed out that the symptoms and lesions of the affection, whatever it might be, were so constant that one was justified in concluding that they arose from the same cause in each case.

The symptoms and lesions, however, were not such as one would expect to arise from a poison; firstly, because the affected animals showed a very high temperature during life—106 to 107 F.; and secondly, because, although the intestine was the seat of the most marked changes, general lesions were found throughout the internal organs.

During the year under report, several outbreaks of the same illness have occurred, and the opportunity of further inquiring into the disease was taken, but, as previously pointed out, little progress can be made in any one year, as the illness seems only to occur during a short season.

A quantity of cut bracken was obtained from pastures in the North of England, where illness amongst the cattle was occurring.

The bracken was fed to heifer No. 249, but, in order to get the animal to consume it, it had to be mixed with a small proportion of cut grass and sharps. Between August 14th and 20th the animal consumed, approximately, 60lbs. of bracken. After the first two meals,

which together contained about 30lbs. of bracken, the heifer showed symptoms of indigestion, but apart from this no toxic symptoms were observed, and the temperature remained normal.

From the 20th August, that is when the heifer had consumed about 60lbs. of bracken, the latter was discontinued in the feed, and the animal was carefully observed during the week following; no symptoms of illness appeared.

In the course of another inquiry, the owner of the animals stated that he believed the disease was caused by a weed which he referred to as "Tormentil."

This weed was identified at Kew as *Potentilla Tormentilla*, Linn.

It is very widely distributed in Great Britain, and is usually looked upon as quite harmless. To obtain further information regarding its effect on animals, a quantity, amounting to about 3 lbs., was removed from pasture on which the disease had appeared, and it was fed to heifer 211 at the laboratory. Eight days after consuming the weed the temperature rose to 103 F., and for a further period of eight days it fluctuated between 102.8 and 104.2 F. Otherwise, however, the animal showed no signs of ill-health, and it was concluded that the feeding experiments had probably nothing to do with the rise of temperature.

A second outbreak of so-called bracken poisoning was reported from Buckinghamshire, and Mr. Jackson, one of the Board's Veterinary Inspectors, who made inquiries on the spot, observed that the same weed was very prevalent on the pastures, and decided to bring back a quantity for further experimental observation.

Between 4 and 5 lbs. of the weed was fed to heifer No. 188. On the evening of the third day, after the weed had been consumed, the temperature of this heifer rose to 106 F., and it fluctuated between 103 and 106 for three days. Coincidentally with the rise of temperature, the animal showed symptoms of decided illness. On the fifth day after feeding on the weed the heifer suffered from diarrhoea, and a considerable quantity of blood was passed in the faeces. The diarrhoea and evacuation of blood continued for three days, after which the animal appeared to be improving, and it was decided to kill her in order to observe whether the lesions attributed to bracken-poisoning were present. She was killed on the twelfth day after receiving the weed. Lesions identical to those found in connection with the outbreaks in the field were present in the intestine, but systemic lesions were absent.

The caecum showed a perfect network of black lines, due to hæmorrhage in the sub-mucous tissue, and a large area of the posterior bowel showed broad longitudinal hæmorrhages not unlike what one sees sometimes in cattle plague and East Coast fever. In the other parts of the bowel many small hæmorrhagic areas were found irregularly distributed. As these lesions were practically identical with those found in animals dying in the field from so-called bracken-poisoning, though they were somewhat less severe, and as they had occurred in an animal at the laboratory, where the disease was unknown, after feeding with the weed known as Tormentil, it was decided to obtain a further quantity from the same place for another experiment. It was arranged that freshly cut Tormentil from the same pasture should be sent to the laboratory daily for a few days. It should be noted here, however, that, whereas we were certain that the weed which was given to heifer 188 had been taken from the place where the sick animals were actually grazing, that sent up later was collected at various places where, possibly, the animals had not grazed when ill.

On September 6th, heifer No. 123 was fed with 4 lbs. of the weed, all of which was eaten. On September 7th, the temperature was normal, but the animal was very dull, and a small quantity of blood was passed with the

dung. On September 8th, 6 lbs. of Tormentil was fed, and on the 9th September the animal received a further quantity of 4½ lbs. The temperature remained normal, and the animal showed no signs of internal disturbance after that noted on September 7th. As no other animals were available for experiment at the time, the observations were not carried further, but it will probably be possible to continue them at a future date, when the disease appears again in the field.

In considering the observations which so far it has been possible to make, the following remarks on the nature of this apparently mysterious disease seem warrantable:—(a) that the high temperature, which accompanies the clinical symptoms, is contrary to what one finds in illness due to poisoning; (b) that the negative results of the experiments described in this report and in that of 1909, in which large quantities of bracken were fed to cattle at the laboratory, furnish a considerable amount of evidence against the opinion that the illness is due to poisoning by bracken; (c) that the fact that a case of the disease was produced in a heifer at the laboratory by feeding on material which contained no bracken, is further evidence against the latter substance being responsible for the illness; (d) that the positive result of the experiment on heifer No. 188 after feeding on Tormentil at the laboratory is by no means to be taken as proving that the illness originates from feeding on Tormentil, which is very widely distributed in this country, and is generally regarded as a harmless weed, especially as one must not neglect the possibility that the illness is due to some form of contagion, which may have been carried to the laboratory with the Tormentil from the pastures on which the sick animals were grazing.

WARBLES.

It has been possible during the year under report to make a number of observations in connection with warbles and the warble-fly. Through the kindness of J. Lindsay, Esq., National Federation of Meat Traders' Association, two cattle, which had been pastured in a warble-fly district during the fly season of the previous year, were sent to the laboratory for observation in April, 1910, that is to say, at the time warbles were distinctly apparent under their skins. The animals had been pastured on marshy land round about Dagenham in Essex. Unfortunately for our purpose, they were not very badly infested with warbles, but a sufficient number—about 20 in all—was obtained to enable some useful observations to be made. The animals were carefully examined from day to day, and as soon as the first nodules showed signs of bursting, the animals were tied up in pens in a glass-house, and visited about every hour during the daytime.

It is well known that flies seldom emerge from warbles which have been pressed out by force from under the skin. It has also been stated by several writers that it is very difficult to observe the warble making a spontaneous exit from the tumour, and to explain this it has been suggested that the exit is made during the night. The experience at this laboratory has been contrary to these statements. Tumours on the skin with gradually expanding orifices were marked, and carefully watched, and in no case was a warble known to make its exit during the night. On the contrary, it was found that exposure to the sun's rays seemed to favour the exit from beneath the skin. Sometimes a warble was ejected with considerable force, owing probably to sudden rupture of the attenuated, restraining, tissue at the surface of the nodule, and in one case the exit was accompanied by a report like that of a pop-gun. In the majority of cases, however, the warbles were observed to wriggle out of

the tumour, and even remain for a little time on the coat of the animal, when the immediate fall from the host's body was not too perpendicular. Once they gained the ground, they were observed to wander about slowly but continuously, until they found themselves in a shady place, when they curled up, and became quiescent. They could be made to curl up almost immediately after exit by covering them with a large pill box, and if they were exposed again to the sun's rays by removing the box before the outer surface of the pupa-case had hardened, they could be observed to start wandering again quite actively. So far as our observations go, the outer skin seems to become quite rigid in less than 24 hours after the warble has been placed in the shade.

The first warble was observed to make its exit on the 31st May, during sunny weather. The others continued to come out until the 12th June. Sixteen of these warbles were placed in a cool, shady room, in special cages made of mosquito netting, and a note was made against each of the date upon which it was obtained from the animal.

Flies were obtained from six of these—

No. of Warble.	Date obtained from host.	Date fly emerged.	Date fly died.
1	May 31	July 3	—
2	June 2	" 12	July 25
3	" 3	" 12	" 29
4	" 12	" 25	" 29
5	" 12	" 5	—
6	" 12	" 5	—

The dates on which flies Nos. 1, 5, and 6 died were not noted exactly, as they died in the same cage, and could not be identified. All three were dead, however, by July 19th.

When kept in a cool and shady room the flies crawled slowly about the cage, but they did not appear to be torpid. When the cages were taken out into the sunshine, however, the flies became very active, and flew about the cages making a loud buzzing sound. Three flies, believed to be one male and two females, were put in one cage, which was suspended in the sunshine. The flies were carefully watched, and attempts at copulation seemed to be made. No eggs, however, were produced, although the flies were given an opportunity to lay on the back of an ox.

Immediately after death the flies were sent to Mr. E. E. Austen, of the British Museum, South Kensington, who was good enough to identify them as *Hypoderma bovis*, Deg.: the species which is said to be least prevalent in this country. Two pupa-cases, which were obtained on the 10th June and from which flies had not emerged, were dissected on the 10th September. Only a dried mass, like solidified liquids, was found in the interior, and no appearance of any fly structure could be found in it.

The average period of time before these six flies emerged was 33·6 days; longest, 44 days; shortest, 23 days. Assuming that the three flies, the dates of whose deaths were not exactly noted (the three died within a couple of days of each other), lived until the 19th July; the average duration of life was 13 days; longest, 17 days; shortest, 4 days. The latter period, however, seems exceptionally short.—*Jour. Board of Agric.*

The beginning of the Barnet Fair, which holds this week, is unknown. Henry II. gave to the Monastery of St. Albans the right to hold a market at Barnet, from which time it has been known as Chipping Barnet, from Ceapon, a Saxon word signifying to buy and sell.

* As Diseased or Exposed to Infection

PTOMAININE POISONING.

By H. J. HUTCHENS, D.S.O., D.P.H. Oxon., M.A. Health Professor of Comparative Pathology and Bacteriology in the University of Durham.

Ptomaine poisoning is a popular rather than a scientific term used to describe an illness following, and attributable to, the consumption of a particular article of food. In nearly all cases the symptoms are of the nature of a gastro-enteritis, and it is further characteristic of the disease that by far the greater number of those who have partaken of the incriminated food suffer from the disease. The term ptomaine poisoning is inexact, because it leads by inference to the assumption that the symptoms are due to ptomaines, while in fact, as will be shown, these substances are not the cause of the disease. The word ptomaine (from the Greek, a corpse) was introduced by the Italian toxicologist Selmi to describe certain chemical substances more or less allied to the vegetable alkaloids which had been found in putrescent meat and decomposing albuminous matter.

BACTERIA AND PUTREFACTION.

In the earlier part of the last century, as the outcome of investigations by Panum and others, it had been shown that substances of a poisonous nature, chemically resembling the vegetable alkaloids, were present in decomposing animal matter, and these substances were later made the subject of an elaborate investigation by Selmi, and later still by Brieger and others. The result was that a number of definite chemical compounds, having many properties in common with one another, were isolated from decomposing flesh, etc. When the relation of bacteria to putrefaction had been proved by Pasteur it was recognised that these alkaloidal bodies were the

products of bacterial activity. And the further researches of Pasteur and Koch, which established the micro-organic nature of the infective diseases of man and the lower animals, gave a great stimulus to the investigation of the products of micro-organisms, because it very soon became evident that the infecting micro-organisms exerted their effects by means of chemical products elaborated by them in the medium in which they happened to be growing, whether that medium were the living body or an artificial culture medium. The truth of this view of the nature of the action of micro-organisms was proved in 1880, when Pasteur showed that by the inoculation of filtered, and therefore sterilised, cultures of the organism of fowl cholera he was able to reproduce the disease in susceptible animals just as though he had inoculated the living organisms.

VARIETIES OF PTOMAINES.

The detection of alkaloidal bodies in unsound meat led to the opinion that the symptoms following the consumption of such meat was directly due to them. This explains the origin of the expression ptomaine poisoning. As the result of the work of Selmi, Brieger, and later observers, a considerable knowledge of ptomaines has been acquired, and a large number have been isolated and their chemical composition determined. Vaughan gives a list of fifty-seven different ptomaines, the majority of which have received names indicating more or less, in most cases, the sources whence they were originally obtained. At first the ptomaines were regarded as characteristic products of the decomposition of animal matter, and the word itself would indicate that this was their origin. The majority of ptomaines have no doubt been obtained from putrescent meat or flesh, but they are also found under other con-

ditions. Muscarin, for instances, is the active principle of poisonous mushrooms, but has also been obtained from decomposing flesh.

WHAT IS A PTOMAINE?

A ptomaine may be defined as "an organic chemical compound, basic in character, and formed by the action of bacteria on nitrogenous matter" (Vaughan).

Ptomaines "are to be regarded as extracellular products of bacterial activity. They do not originate within the bacterial cell, and therefore are not to be looked upon as direct metabolic products of the cell protoplasm, but rather as secondary cleavage products." Many of the ptomaines belong to the benzene series and are derivatives of pyridine; others are hydro-carbon derivatives. Most of them, either in their chemical or physiological reactions resemble the vegetable alkaloids. "Some may be obtained from a variety of decomposing substances, irrespective of the type of organisms present." They cannot, therefore, be regarded as the specific products of bacteria. They are found in only very small amounts in decomposing animal matter, and it is only when meat is in so advanced a stage of decomposition as to be totally unfit for human food that they are present at all.

Moreover, many of the ptomaines are non-poisonous, and the majority of those that act as poisons exert their influence on the nervous system rather than on the alimentary system, which is further evidence against their being the cause of the symptoms of food-poisoning, since in the great majority of cases the latter are of the nature of a gastro-enteritis. (There is, of course, a definite class of epidemics of food-poisoning, in which the active substance is of the nature of a neuro-muscular poison. This, however, is not a ptomaine, and reference will again be made to this particular form of food-poisoning under the head of Botulism.)

FOOD POISONING.

On various grounds, therefore, ptomaines can no longer be considered to be the cause of food-poisoning. It would perhaps be exceeding the limits of what has been definitely established experimentally to say that ptomaines never cause symptoms of food-poisoning, but all the available evidence is against their playing any part in the production of those symptoms. The ptomaines have, therefore, largely lost their interest for the bacteriologist. But to the toxicologist they are of supreme importance, to which fact the recollection of a recent criminal trial will bear witness.

Food-poisoning is now attributed to the specific poisons of bacteria. Chemical investigation has shown the presence in culture media in which bacteria have been grown of numerous substances of a highly complex nature, ptomaines, tox-albumins, albumoses, etc., but all attempts so far to determine the nature of the specific bacterial poisons by chemical means have failed.

TOXINS.

The specific products to which the action of bacteria on the tissues is due are known by the generic name *toxin*. Toxins differ from all such substances as ptomaines, tox-albumins, etc., in that they are specific. They are "the result of synthetical processes occurring within the bacterial cell." Bacterial toxins are the most poisonous substances known. It has been shown, for instance, that 1 c.c. of a particular broth culture of tetanus contained 0.025 gramme of organic matter, and that that quantity contained sufficient toxin to kill 100,000 mice. Even assuming that the whole of the 0.025 gramme of organic matter was toxin, which of course it was not, the example serves to show the extremely poisonous nature of bacterial toxins.

It is to these toxins that the symptoms following the invasion of the body by bacteria are to be attributed. And when it was shown that food-poisoning could not

be regarded as a ptomaine effect it was thought that the symptoms must be due to bacterial toxins present in the meat. This is undoubtedly true in some cases. But Gärtner's observations during an epidemic of food-poisoning at Frankenhausen in 1888 showed that food-poisoning was at least sometimes an infective disease. And, as a matter of fact, in most cases food-poisoning is a specific infective disease, and is the result of poisoning by bacterial toxins. The toxins may be present in the food before it is eaten, or they may be elaborated in the human body. The former condition gives rise to a toxæmia while the latter is a true infection, resulting from the ingestion of organisms contained in the food which has been eaten. The latter condition is due to a small group of organisms known as the "enteritidis" or *Salmonella* group, the members of which are bacteriologically closely related to the typhoid and colon bacilli. It is possible that occasionally they gave rise to a toxæmia, but in the great majority of cases food-poisoning due to these organisms is an infective disease.

Food-poisoning is, therefore, the result of the action of the specific toxins of bacteria on persons who consume meat or other food infected with living organisms or their toxins, or both. The non-specific products should also, perhaps, be included; for though the evidence so far available is against the view that they take any part in the production of food-poisoning, it cannot be stated as a definitely ascertained fact that they never exert any influence. This definition at once excludes from the category of food-poisoning all cases of poisoning following the consumption of food containing arsenic, lead, strychnine, or other well-defined chemical substance, whether administered intentionally for criminal purposes or taken by accident. On the other hand, the generally accepted use of the term does not include such diseases as enteric fever, Malta fever, etc., though these are also the direct result of eating food specifically contaminated with the organisms of those diseases.

(To be continued)

On the Value of Combination.

In his address to the N.V.A. at Carnarvon, Mr. T. Salusbury Price, in commenting on the scheme for the affiliating of the veterinary societies, referred to the action of the British Medical Association in connection with the National Insurance Bill. The following extract from the address by the President B.M.A., Mr. Robert Saundby, carries the subject a little further.

"The National Insurance Bill is admittedly an adaptation of the German law of 1885, and a parliamentary paper has been circulated (Cd. 5679) containing the opinions of various authorities in Germany in support of the proposed legislation. With equal reason we may look to Germany for warnings and danger signals, and I would point out that the effect of placing the administration of medical benefits in Germany in the hands of committees controlled by working men has been to cause a bitter quarrel between the two parties, and has led to the formation in Germany of a medical organization with a membership of 21,210, known as the Leipzig Union (*Leipziger Verband*). Its object is to meet organization by organization, to create a fund for fighting purposes, and to form a league for conducting an agitation in the event of any action on the part of the societies contrary to the interests of the medical profession. It is, in fact, a trades union founded on the same lines and having similar objects to those of the workmen, and ready to use the same means, namely, a strike, to gain its end. Our German colleagues claim that although this has been said to be unworthy of a liberal profession, it is the necessary outcome of the situation created by Parliament, which has sought to

benefit the wage earners at the expense of the medical profession. So far the Leipzig Union has been victorious in all the contests in which it has been engaged, the best part of the medical profession having rallied absolutely under the banner of professional union. Those who have remained outside are only army doctors, university teachers of theoretical subjects, doctors without practice, and a few cautious medical bureaucrats; and no one knows better than the leaders of the workmen's societies and the directors of the insurance companies that they must rely only upon the most incapable medical aid should they quarrel with the medical profession.

What has been done in Germany can be done here. If Parliament forces a fight upon us we are not unorganized. The British Medical Association, which was founded with quite other objects, has been compelled by the militant tactics of the friendly societies and clubs to create a department for the defence of medical interests, and this is conducted with great ability by the Medical Secretary, Mr. J. Smith Whitaker. During the past year and owing to the threatened danger, over 3,000 new members have joined our ranks, and approximately we number to-day 24,400 members.

An Antirabic Vaccine.

The preparation of a safe and efficient antirabic vaccine has engaged the attention of Lieutenant-Colonel Sir D. Semple. His object was to secure a vaccine which would confer a high degree of immunity, be free from risk, and at the same time be capable of ready transportation without fear of deterioration. The methods most commonly practised at present (Pasteur's and Högges') involve the injection of actual living virus, attenuated or diluted. They have been found quite satisfactory, but the introduction of a living virus is not free from objection if it can be shown that a dead virus is equally efficient. The technical difficulty was to discover the best means of killing and preserving the virus without destroying its immunizing properties. The alternatives of heat and antiseptics were discussed, and from previous experience with antityphoid vaccines, it was decided that an antiseptic such as carbolic acid was the most satisfactory agent. The method which Semple advocates is to make an 8 per cent. dilution of rabies virus in normal saline, to which 1 per cent. carbolic acid is added, and to keep this at a temperature of 37 C. for twenty-four hours. By this means the virus is killed. The mixture diluted with an equal bulk of saline solution gives a vaccine containing 4 per cent. virus and 0.5 per cent. carbolic acid. This was found to confer a high degree of immunity on monkeys, dogs, and rabbits, and the serum obtained from these animals had a well marked rabicidal action on living virulent virus. Its efficiency is therefore unquestionable, and is apparently as great as that obtained by the use of living virus. It retains its power for some time, and can therefore be conveyed considerable distances. The method was intended primarily for use in India.—*B.M.J.*

Nuclear Structure of Bacteria.

An important contribution to our knowledge of the nuclear structure of bacteria has recently been made by C. C. Dobell. Owing in some measure to difficulty of technique, the idea has become widely spread that bacteria, as a rule, are enucleate cells, but Dobell points out that in all bacteria which have been adequately studied some form of nuclear structure has been demonstrated. The morphology of the nucleus varies to a surprising extent, not only amongst different varieties of bacteria but also at different periods in the life of the same species. Judging by the changes in the nucleus, it may be deduced that the bacteria are not so simple as might

appear, but that a more or less complicated life-cycle occurs. The various forms which the nucleus assumes may be summarized as follows: There may be a definite system of chromidia or chromatin granules, or there may be one or more aggregated masses of nuclear material. Again, the nucleus may take the form of a filament disposed in various ways; it may be branched or it may consist of strands or bent rods. Finally, it probably also occurs in the vesicular form characteristic of many other plants and animals. Mr. Dobell's conclusion is that we have no reasonable evidence to warrant the belief that enucleate bacteria exist. Investigations on the same subject have been made by H. Pénau, and in his latest publication he deals with the cytology of the anthrax bacillus. He recognizes a well-marked cycle of development in which five stages can be differentiated. At first the cell consists of an almost homogeneous mass of protoplasm which stains with basic dyes. After twelve hours' growth the nucleus appears at one pole as a definite body, which readily takes on nuclear strain. In the next stage it is replaced by a basophile reticulum, which gives the bacillus a vacuolated appearance. In about three days this reticulum becomes broken up into beadlike masses which collect together. The aggregate becomes more and more discrete, and eventually assumes an ovoid or globular form; finally it appears as the spore. According to Pénau, therefore, the spore is the direct descendant of the nucleus.—*B.M.J.*

Personal.

BRYDEN.—On Sept. 2, at 73 Bishop's Park Road, Fulham, the wife of R. Bryden, F.R.C.V.S., of a son.

OBITUARY.

WILLIAM OWEN WILLIAMS, F.R.C.V.S., The University, Liverpool.

Graduated, New, Edin: April, 1881.

Prof. Williams, F.R.C.V.S., F.R.S.E., was born in Bradford, Yorkshire, in 1860, he was the son of the late Prof. William Williams, Principal of the New Veterinary College, Edinburgh. It was at this College that Prof. W. Owen Williams received his first instruction in veterinary science, which he supplemented at the Alfort Veterinary College, Paris. Returning to Edinburgh he rejoined the New College, becoming hospital surgeon and demonstrator, then Professor of Veterinary Medicine and Surgery as applied to the ox, sheep, pig, and dog, and finally Principal in 1900. He was President of the Council of the Royal College of Veterinary Surgeons, 1902-4, and President of the National Veterinary Association in 1905-6. In 1904 he accepted the Professorship of Veterinary Medicine and Surgery in the University of Liverpool. From 1903 Professor Williams had been Veterinary Surgeon to the Establishment of King Edward's and King George's Stables. Prof. Williams was the author of many contributions to veterinary science. He edited a work on the "Principles and Practice of Veterinary Medicine and Surgery," had been Editor of *The Veterinary Journal*, and revised Fleming's "Operative Surgery," vol. II. During the Boer War Prof. Williams acted as supervisor of horses sent out by the War Office.

Prof. Williams married in 1885 Annie Christine, daughter of Mr. John Flint, of Glasgow, by whom he had two sons and a daughter. He had been in ill-health for some days, and died suddenly, while talking to his son. His age was 51 years.

AARON SISSONS, M.R.C.V.S., Whinnah, Lamplough, Cumberland. Graduated, Edin: April, 1870.

Death occurred on August 18th, at his residence, from general paralysis. Aged 69 years.

CORRESPONDENCE.

DISEASES OF THE DIGESTIVE ORGANS
IN THE OX.

Sir,

I must thank Mr. Mayall for his courtesy in replying to my queries, and beg to state that his explanations and views on the above will prove of marked assistance to me in the work on which I am engaged.

With reference to the queries of "Enquirer" unfortunately I am in the humble position of querist myself, and am seeking for information. However, in reply to Query 1, I should say that the ingesta in the omasum is *not always* dry and in the form of leaves, as I have examined the organ on several occasions and found the contents quite soft, in fact succulent in some cases.

I think the proper authority to answer this query would be an inspector of abattoirs, who has ample opportunities of observing the condition of this organ in normal animals.

With regard to the mucous, epithelial, or papillary membrane peeling off easily, I have not observed this in the omasum, but I know that it does occur in the rumen, if the organ is not examined until some time after death.

Query 2.—This to a great extent depends on the answer to query 1. I doubt the existence of such a condition as impaction of the omasum, but as there are many degrees of dryness, it is difficult to know where to draw the line. If the functions of the other divisions of the stomach are in abeyance, one would expect to find the contents of the omasum hard and dry.

The answer to the last query is—No, but there must be a number of veterinary surgeons who have paid attention to the condition of the omasum in a normal state, and who have opportunities of doing so. It was with a view to obtain definite information from a number of such observers that I put forward the queries, and I am hopeful that some useful information may result.

The opinions of observant practitioners are of far greater value than the information derived from text books, as many of the latter follow on the lines of their predecessors.

—Yours, etc.,

Sept. 2.

E. WALLIS HOARE.

"SIDE-LINES" IN PRACTICE.

Sir,

I agree with many of the remarks made by your old and respected correspondent "Old Obadiah," who, I am glad to see, has once again come out of his hibernation to give us a few of his choice "tit-bits."

The young veterinary surgeon should obtain a fair knowledge appertaining to the smaller things of veterinary practice; he should try his hand at some of the Aristotlean operations, such as pig, cat, and dog spaying, caponizing, lamb cutting, etc., even if he relinquishes such work after obtaining the mastery of them. There is no disgrace in doing any small, if done honourably, and they often lead to higher things or aspirations. Pasteur studied the diseases of beer, silkworms, and grapes which led him to discover the true nature of the infectious diseases of man and animals. Jenner studied old women's talk which led him to put vaccination on a sound basis. Darwin studied earthworms, flowers, etc., and from the conclusions drawn from them revolutionised modern thought and gained for himself the title of the greatest mind of the Victorian period.

These few illustrations may depress the prig or conceited fool, but will perhaps give the ambitious hope.

As to avian pathology there is a wide scope and the knowledge gained from a study of it might be adopted for veterinary and human practice. But attention should also be given to the normal animal during life and after death. The examination of fish, reptiles, all classes of birds and the lesser mammals after death will frequently open his eyes and make him put on his thinking cap, especially as regards parasitism. As it is now, his post-graduate study is too narrow and, in consequence, his view of things, physiological and pathological, becomes very limited. The means, however, are generally at hand, but the opportunity is rarely seized.

Concerning "Old Obadiah's" statement that no book on avian diseases, beyond the one brought out by Dr. Salmon in 1899, has appeared from the pen of a veterinary surgeon, I believe that is not quite correct, because as a matter of fact there are several, but perhaps out-of-date. Certainly there are many first class articles on the infectious diseases of birds that have appeared, from time to time, in the various veterinary journals, and which have been penned by such eminent authorities as Sir John McFadyean, Bang, Perroncito, Cettani, Marcone, Tartartowsky and Marx and Sticker, and many others too numerous to mention. Even several papers on the same subjects have been written by young Colonial and continental veterinary surgeons, who have not thought avian pathology beneath them. As it was, avian pathology revolutionised our ideas of immunity and lead up to the present state of our knowledge. Surely this should be enough for "Old Obadiah," unless he wants to see a good modern book, written by a practical man, having had a scientific training and with a wide range of knowledge. It is quite true there is room for such a book. But where is the man? There are plenty of pot-boilers.

Respecting parasitism in birds and other animals, I believe its importance has been *unduly inflated*. I read in the recent report on "Grouse disease" that 95 per cent. of the healthy birds also harboured the *Trichostrongylus pergracilis* (Cobbold, who was also my preceptor, was content to call it *Strongylus pergracilis*) in their system! Cobbold says "As regards the so-called 'grouse-disease,' during one season it may be due to tapeworms, during another to strongyles, during a third to both these parasites. Unfortunately, other avian epizootics, not necessarily due to parasites of any kind, may be mistaken for helminthic epizooty." (*Parasites of Man and Animals*, 1879.)

I have given a little attention to parasitism in birds and other animals killed when apparently healthy or died from disease, and rarely found parasites absent, providing no vermifuge had been administered during life.

I am not speaking from imagination nor worshipingly following the teaching of authorities when I repeat with all seriousness that the effect of parasites on animal life is greatly exaggerated. Their presence, however, is an easy explanation of the cause of disease.—Yours, etc.,

ENQUIRER.

CAN R.P.s. USE V.S.? NO.

Sir,

I have lately come across two certificates issued by a Registered Practitioner who uses the title V.S., I have had legal opinion on the matter, and the result is that the use of V.S. by a registered practitioner is a direct infringement of the Veterinary Surgeons Act, 1881, Sections 15 and 16, where it is stated that "no person registered under this Section shall be deemed to be a member of the Royal College." Section 16 says: "If after the passing of this Act any person not being a Fellow or Member of the Royal College of Veterinary Surgeons takes or uses any name, title, or addition by letters placed after his name is liable to a fine of £20."

Here we have a man usurping a title to which he has not the slightest legal claim, and is endeavouring to hoodwink the public by flying colours to which he has not the most remote title, or even, I hope, will have.—Yours faithfully

M.R.C.V.S.

BLACKLEG

(QUARTER-EVIL. SYMPTOMATIC ANTHRAX.)

The New Zealand Official Report on Blackleg shows that the mortality from this disease has been reduced by 75 per cent. since vaccination was made compulsory. The vaccine is supplied in convenient form under the name of

"BLACKLEGGOIDS."

"Blacklegoids" are easily administered by means of the "Blacklegoid" Injector.

Extract from a letter which appeared in *The Veterinary Record*, January 25, 1908: "About five years ago I commenced to inoculate with Parke, Davis & Co.'s 'Blacklegoids,' and since then I have lost only one, and that was this year, out of over 900 inoculated since I commenced. I may mention that I have no interest in Parke, Davis and Co.'s preparations."

Co. Kilkenny, December 28th. 1907.

The Stock Inspector of the Pastures Protection Board, Singleton, Australia, when ordering (May 17, 1907) 200 doses of "Blacklegoids," stated: "This is the third year I have used your 'Blacklegoids,' with a result far better than I or the owners of the cattle ever anticipated. I do not know of an instance where it did not act as an immediate preventive."

Further particulars will be sent on request by

PARKE, DAVIS & Co., 50 Beak St., Regent St., London, W.

Telegraphic and Cable Address—"CASCARA, LONDON."

Orders for single copies by post, or short subscription (4 weeks (1/2) etc.), should reach this office by first post on FRIDAY MORNING.

The Record is posted to *Subscribers* on Friday, usually in time for the 5 p.m. collection. The normal issue consists of 16 pages of literary matter but this is varied to 20 or to 12, as may be required.

THE 'RECORD' PRECISION SYRINGE.

The FINALITY of Hypodermic and Serum Syringes.

"The "Record" Precision Syringe is a piece of delicate mechanical workmanship well deserving its name. It meets **all requirements as regards aseptic conditions and accuracy and it is always ready for use.**

It consists of **metal and glass** only. The glass barrel is ground inside perfectly true to cylindric form. The Nickel vacuum piston is "ground in" into the glass barrel by precision machinery so as to fit hermetically, it slides smoothly, yet tightly, **without any lubricant.**

The cover is fixed on the cylinder with a **bayonet-fastening**; for the purpose of **thorough cleaning** it is provided with a segmental incision, by means of which it can be detached from the piston-rod by sliding it off side-ways. When **completely** taken apart the Record Syringe **forms 3 parts only: cover, piston and barrel.**

The **Needles** are provided with the original "Progressive" flat mounts. By this arrangement a good hold is afforded to the operator.

The fixing of the needle itself in the mount, by means of a smooth longitudinal guide arranged above the screw threads prevents the needle from breaking off in the mount.

EVERY SYRINGE IS GRADUATED BOTH IN C.C. AND MINIMS.

Price with 2 Steel Needles in Metal Case—20c.c. 21/- 10c.c. 17/6. 5c.c. 15/- 2c.c. 10/- 1c.c. 9/-

THE UNIVERSITY OF LIVERPOOL

Veterinary School,

NEXT SESSION COMMENCES SEPTEMBER 28th, 1911.

Diploma of Membership of the Royal College of Veterinary Surgeons.

The Examinations for this Diploma are conducted at the University. Complete courses of instruction are given in the several subjects of these examinations, and are specially designed to meet the requirements of students preparing for the Diploma. Excellent facilities for practical hospital training are afforded in the three large hospitals attached to the School.

The University laboratories are completely equipped, and provide exceptional opportunities for the practical study of the various subjects of the curriculum.

Post-graduate Courses.

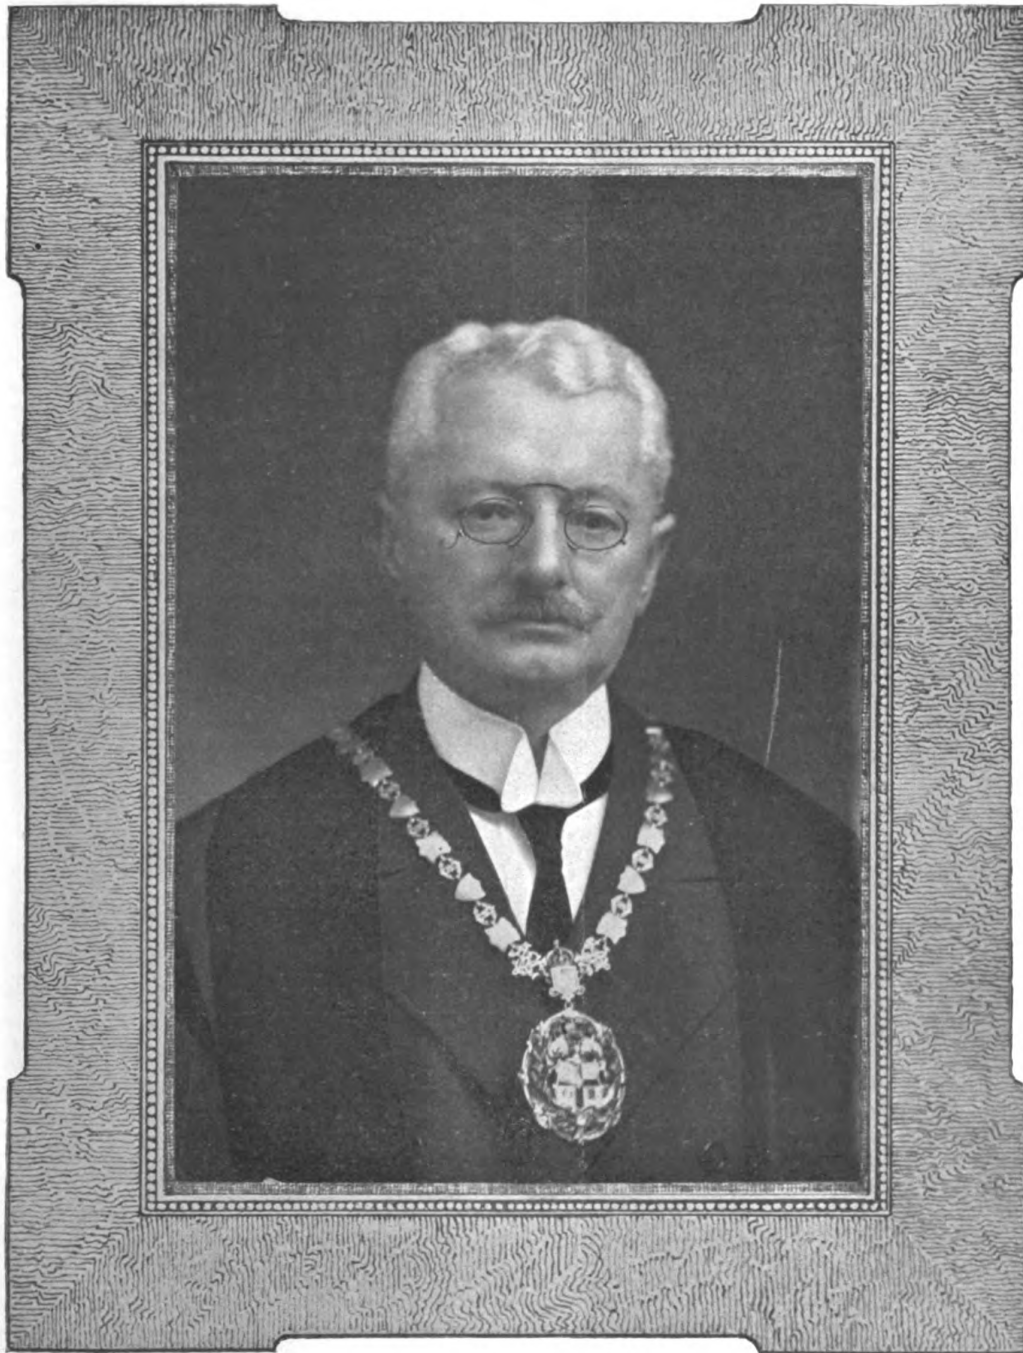

Courses in Comparative Pathology, Bacteriology, &c., are specially arranged for officers of the Army Veterinary Department, Colonial Veterinary Surgeons, and others.

D.V.H. Course. This Course taken during the Autumn and Lent terms, qualifies for the examination for the Diploma of the University.

Full particulars as to Preliminary Examinations, &c., together with prospectus, may be obtained on application to—

J. SHARE-JONES,

Secretary to the Board of Veterinary Studies.

Elliott & Fry.

Prof. W. O. WILLIAMS, F.R.C.V.S., F.R.S. Edin.

Professor of Veterinary Medicine and Surgery, Liverpool University.

THE VETERINARY RECORD

A Weekly Journal for the Profession.

EDITED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1210.

SEPTEMBER 16, 1911.

VOL. XXIV.

Professor Owen Williams.

There is a disadvantage in being the son of a great man, or even in bearing the name of the very eminent. No one of the name of Gladstone can hope to be very prominent after W. E. Gladstone. So with Professor Owen Williams. Until his father's death in 1900 he was comparatively unknown outside of Edinburgh. There were two Professor Williams at the New Veterinary College, but the father's reputation and position overshadowed the son to such an extent that there might have been only one so far as name and fame were concerned. On the death of Principal Williams his son Owen became principal, and much anxiety was felt by his friends as to his ability to successfully conduct the institution, which was not left in a strong financial position. But Owen Williams rose to the occasion and showed himself possessed of business qualities and force of character quite unsuspected. He conducted the New Veterinary College up to the time it was transferred to Liverpool with marked success, and his students continued to exhibit the same proficiency in clinical medicine and surgery that had marked the men under his father's tuition.

Owen Williams had attempted to bring about some connection between veterinary science and the Universities for years before the question was taken up by Professor Rubert Boyce, and it was quite in accordance with the fitness of things that when Liverpool University offered to embrace a veterinary faculty, he should throw in his lot with the adventure. It was pointed out at the time that the public requirement for veterinary surgeons was not increasing, and that the establishment of more veterinary schools was hardly warranted, even if they were under the ægis of a University. However, seven years have passed since then and the Liverpool Veterinary School is still alive and active.

Professor Owen Williams graduated in Edinburgh in 1881, and afterwards continued his studies at the French Veterinary School at Alfort. Returning home he joined the teaching staff of the New Veterinary College. In 1886 he took the Fellowship degree. In 1894 he was elected a Member of Council of the Royal College of Veterinary Surgeons, and became a Vice-president in 1898.

In 1902 he attained the highest position in the veterinary profession—President of the R.C.V.S.—and so well did he fill the office that the Council re-elected him for a second term—an honour seldom offered to anyone. He has played many parts in his professional life, and in all has shown grasp of the situation. When the South African war took place he patriotically offered his services

and was sent to the United States to assist in the purchase of transport animals. On this job he had the initial difficulty of organising the work, and had only succeeded in overcoming it when he nearly lost his life from an attack of typhoid fever.

For some years he edited *The Veterinary Journal* with conspicuous ability. He also edited more than one edition of his father's well known works on Medicine and Surgery. Fleming's "Operative Surgery," Vol. II., was a work he saw through the press, and made complete by writing the last few pages which the author was prevented by death from finishing. He contributed a number of papers to local veterinary societies, and was President of the National Veterinary Association.

Prof. Owen Williams' untimely death at the early age of 51 leaves the veterinary profession poorer, and although it is not probable that he would have added much to original research had he lived, he would certainly have done good work in his professional position in instilling into future graduates sound practical knowledge of medicine and surgery.

In private life Owen Williams was a good friend and pleasant companion. He had been given a liberal education, including terms at the University of Edinburgh; he possessed far above the average intellect, was well read, and had a sense of humour, which is a saving grace in all men. He leaves a widow, two sons and a daughter, with whom the most sincere sympathy for their irreparable loss will be felt by a very wide circle of friends.

At the funeral, which took place last Saturday, there was a large attendance of friends and colleagues from the University and the veterinary profession.

Our portrait presents the Professor in his official state as President of the Royal College of Veterinary Surgeons.

CIVIL VETERINARY WORK IN BENGAL.

This week we publish a Government resolution on the annual report of the Veterinary College and Civil Veterinary Department of Bengal for the year 1910-11. The resolution is itself a condensed report of the various activities of the Bengal Civil Veterinary Department, among which is the Bengal Veterinary College, directed by Colonel Raymond, I.C.V.D. Its concluding clause is an emphatic official commendation. "The Lieutenant-Governor in Council congratulates Col. Raymond on another year's efficient administration, and thanks him for the care and tact which he has displayed in the conduct of his duties." This is not the first official recognition of the merit of the civil veterinary work of India that we have heard of late, and, like the others, it shows that the C.V.D., is gradually becoming more patently valuable to the country.

The document enters in some detail into the year's work in Bengal, which may be pronounced highly satisfactory. Even in the one direction in which the need for further improvement is most emphasised, the conditions show an advance upon those of former years. Slackness in reporting outbreaks of disease, and hostility to inoculation methods still remain in some districts, but the mere fact that the inoculations performed during the year under report have about doubled the total of the preceding one shows that the population is becoming less prejudiced.

No native opposition seems to have been encountered in Calcutta and its neighbourhood, where the control of epizootic diseases is conducted by Col. Raymond himself. Rinderpest, foot-and-mouth disease, and glanders, while not very prevalent, are nevertheless in evidence in and around Calcutta, and cast a heavy additional responsibility upon the Principal of the Bengal Veterinary College. Glanders, we notice—so far as the number of infected stables is concerned—declined more than 33 per cent. during the year under report, thus diminishing to much the same extent as it did here during the same period.

The progress of the Veterinary College and its hospital, and also that of the Raymond Research Laboratories, seems altogether good. So far, unfortunately, the various outlying veterinary dispensaries scattered throughout Bengal, have made no great headway in gaining the confidence of the natives; but they are certain to do so in time. The C.V.D. in Bengal increased its staff numerically during the year; and every additional inspector or assistant means one more factor in overcoming popular prejudice.

In the meantime, Col. Raymond and Mr. Quinlan may be congratulated upon their twelve months' work. "Another year's efficient administration," such as this is admitted to be, marks a further stage in the development of a Department which, though still young, is already becoming invaluable.

ACTINOMYCOSIS.

The accompanying photographs illustrate the appearance presented by a typical case of actinomycosis which recently came to the notice of the writer when in the vicinity of Cape Town, South Africa.

Figure 1 shows the cow's head—the subject of this short note—prior to slaughter. As will be seen the case was a very well marked one, both rami of the lower jaw being extensively involved in the diseased process. In figures 2 and 3—microphotographs from a section of the diseased tissue shown in figure 1—are depicted three colonies of the streptothrix actinomyces, each surrounded by round cells and leucocytes, and externally by fibrous tissue; whilst figure 4, likewise a microphotograph from the same section, shows the edge of one of the colonies—the radiating club-like elements are here well in evidence.

One does not for one moment claim that this particular case differed in any respect from the textbook description of the malady. The photographs are here reproduced merely in the hope that they may be of some slight interest to readers (more especially to the younger ones) of *The Record*, illustrating, as they do, a well marked and typical example of infection with the streptothrix actinomyces.

WALTER JOWETT, F.R.C.V.S., D.V.H.

TOXIC DOSE OF SULPHUR.

On Monday last I was called in to a 14 hands cob with the history that the owner had given him $\frac{1}{2}$ lb of sulphur (after having weighed it) in his food, on the previous day at 12 o'clock, "to cure proof worms."

I saw the cob at 8 p.m., 20 hours after having eaten the sulphur, he was then showing colicky pains, very offensive diarrhoea, extremities cold, pulse quick, almost imperceptible, and died at 12 o'clock, just 18 hours after having taken the sulphur.

I have had several deaths from sulphur poisoning, but have never before known the exact amount given, and I thought this case worth recording on that account.

CHARLES E. PERRY, F.R.C.V.S.

Bristol.

ABSTRACTS FROM FOREIGN JOURNALS.

UMBILICAL TUMOURS AND UMBILICAL INFLAMMATION IN THE CALF.

Gmelin has stated that neoplasms at the navel are very rare in the domestic animals, and do not occur in ruminants to his knowledge. Gustav Rozsa, however, now describes (*Allatorvosi Lapok*) two such cases which he has recently observed, both in bull calves of three weeks old. In one case the tumour was two inches long, 4-10th inch thick, bright red in colour, and situated hat-like upon the stump of the umbilical cord. In the other case the tumour showed no rim-like edge, but its colour was similar to that of the first one. The tumour divided like the fingers over the abdomen; and, upon section, it seemed to be composed of firm connective tissue. In both cases excision with the knife was practised with success. The tumours, in common with the stump of the umbilical cord, were removed; the wounds were sutured; the sutures were removed on the third day; and healing was complete in two weeks. The author adopted the plan of protecting the wound with an antiseptic bandage, in order to avoid contamination by urine and straw.

The purulent inflammation of the navel in calves, according to Rozsa's experience, is not so serious a disease as many suppose, if it is subjected to timely and adequate radical treatment. The symptoms are

Fig. 1.

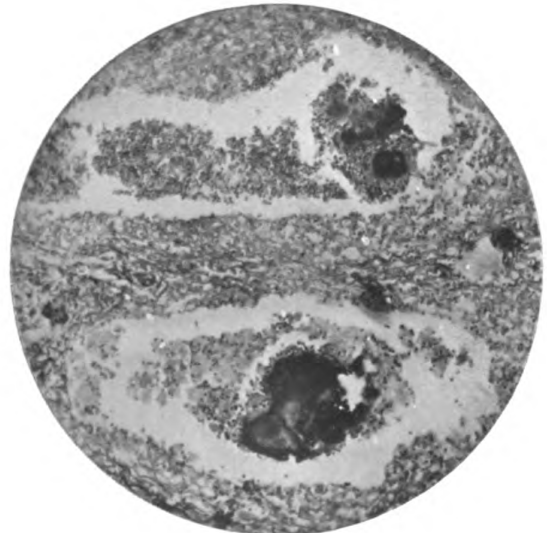

Fig. 2.

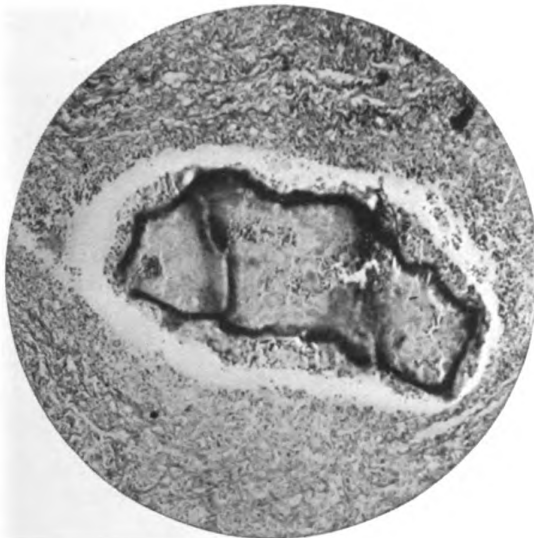

Fig. 3.

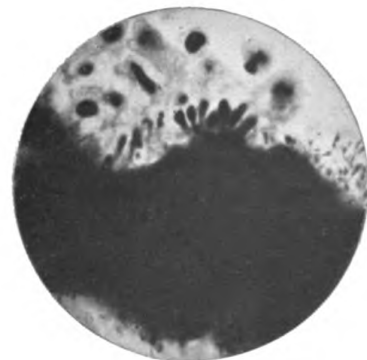

Fig. 4.

Cow's Head: 2, 3, Sections of the diseased tissue:
4, Portion of same section, showing "clubs."

ACTINOMYCOSIS.

Note by Walter Jowett, F.R.C.V.S.

dulness and loss of appetite; the navel string is uniformly swollen, warm, and painful; grey-brown greasy crusts are found upon the stump of the navel string; and the neighbouring tissue is similarly infiltrated, and is malodorous. The treatment should be operative in every case. The animal should be placed in the dorsal position, and the field of operation adequately prepared. The stump of the navel string, with the skin attached to it, is then removed; and the whole cavity is thoroughly scraped out with a curette, in which process a considerable quantity of malodorous, greasy, grey-brown, necrotic tissue is always removed. A tampon of wadding of a suitable size is then placed in the cavity, and an antiseptic bandage applied over the whole. Recovery takes place without any further treatment, and is so rapid that the calves begin to suck soon after the operation. The cause of this disease is uncleanness; and Rozsa mentions that in his district it is customary to pay no attention to the navel string, and to allow the cow to lick it off. In the case of bull calves, the urine reaches the navel during urination; and on that account diseases of the navel are more common in bull calves than in heifers.—(*Berliner Tier. Woch.*)

PAPILLOMATOUS DERMOID CYST IN A DOG.

Roquet records (*Journal de Méd. Vét. de Lyon*) the following case in a two-year-old dog. The animal showed a circumscribed swelling, of the size of a pigeon's egg, upon the left side of the root of the penis. The skin in this region was extensively ulcerated, and a fistula existed—the latter being very short in its course, indurated at its edges and surrounded by a zone of slight inflammation, and giving exit to a not very abundant purulent exudate.

The dimensions of the exterior orifice of the fistula rendered the extirpation of the cyst very easy. It was enucleated without difficulty by the aid of digital pressure.

The neoplasm was found to be oval in shape and surrounded by a membrane of connective tissue, which was greyish white, not very thick, and elastic in consistence. When incised, it was found to be filled with a creamy, spangled, somewhat nacreous substance, which the author compares to boric acid in its aspect. The internal face of the cyst-wall was also spangled and nacreous; but, when all material of this nature had been removed from it by means of a jet of water, it showed filiform projecting papillæ of from $\frac{1}{4}$ inch to 2-5th inch long.

The cyst-contents, when microscopically examined in a drop of glycerine without staining, were found to consist of small epidermal scales, free or joined together, colourless and brilliant, detached from the internal face of the cyst-wall.

The cyst-wall, throughout its extent, possessed the simple structure of the skin without pilo-sebaceous follicles, but with very long filiform dermal papillæ covered with very well developed stratified horny epithelium. The great number of these papillary projections had given the internal face of

the cyst-wall its foliated papillary aspect to the naked eye. Histological sections of a fragment of the cyst-wall showed the characters of a horny papilloma.—(*Annales de Méd. Vét.*)

PHLEBOTOMY IN AZOTURIA.

Wyssmann (*Schweizer Archiv*) after summarising the views of different authors upon the effects of phlebotomy, declares that it is of the greatest utility in azoturia. In serious cases of this affection, the practitioner always finds dyspnea, with a profound alteration of the pulse; the respiration is always accelerated and often difficult. It is therefore comprehensible that phlebotomy should be useful in facilitating the cardiac and pulmonary functions.

After practising phlebotomy in cases of azoturia, the patients almost always become much calmer. In every case, the bleeding not only produces a mechanical effect, but also has an action in eliminating a certain quantity of toxic products from the organism. It is known that bleeding stimulates the urinary secretion and thus indirectly favours the elimination of products of denutrition; and this effect is obtained much more rapidly and completely by phlebotomy than by the administration of medicines.

Moreover, von Hoesslin has demonstrated experimentally that each bleeding is followed by the passage of a certain amount of sodium chloride from the lymphatic system into the blood, and that this is quickly followed in its turn by the elimination of a portion of the products of denutrition which act toxically, and which can only leave the organism by the urinary passages. It is probable, also, that the effects of bleeding in azoturia should be partially attributed to the specific action of hæmorrhage upon the blood-forming organs, such as the bone marrow and the spleen.

Wyssmann also relates his own personal observations of azoturia, which are based upon 43 cases. Of these 37 occurred during the winter months, and six only during the summer ones. The author deduces from this that chill, if it is not a direct cause of azoturia, at least acts as a predisposing condition.

All these 43 cases were bled at the jugular, and the amount of blood taken varied from 4 to 8 litres (approximately from 7 to 14 pints). In 10 horses, bleeding was practised when the animal was already recumbent; and 7 of these cases succumbed to the disease. The other 33 horses were bled while they were still standing, and only one died from azoturia. The percentage of mortality for the whole 43 cases is therefore 16.4%, and it is notable that, in animals bled when recumbent the mortality reached 70%, while it was only 3% in the case of those bled while still standing.

It is important, of course, to stop all work as soon as the first symptoms of azoturia appear. The author, however, has met with serious cases in which, though the horse was still standing, dyspnea was violent and transpiration abundant, and in which, by immediately having recourse to copious bleeding, he has enabled the patient to travel for

another half-hour. He remarks that this would have been impossible without bleeding.—*Annales de Méd. Vét.*

(Wyssman's belief that "chill" is a very important, if not the main factor, in the causation of azoturia, is one which is very largely held among Continental veterinary surgeons.—TRANS.)

BRONCHIAL LITHIASIS.

V. Ball (*Journal de Méd. Vét.*) has observed this affection in a thirteen-year-old cat. The animal had shown fits of coughing corresponding to veritable calculous crisis, and had finally developed dyspnoea, loss of appetite, and emaciation. The author remarks that the expectoration of a broncholith by the cat, if it had occurred and had been observed, would have established the diagnosis as it does in the case of the human patient. This cat finally succumbed to a crisis of asystolism with pulmonary oedema.

Post-mortem, partial atelectasis of the middle and anterior lobes of the lung was found. The lungs showed slight passive congestion, with oedema; and some centres of active congestion were also found. The right anterior lobe showed a small hæmorrhage, which was adjacent to a centre of chronic broncho-pneumonia, the latter being yellowish-grey in colour, mamillated upon its surface, and measuring 1 1-5th inch long by 4-5th inch broad.

This broncho-pneumonic centre was situated in the region adjoining the pedicle of the pulmonary lobe in question. When it was sectioned transversely, the pulmonary tissue showed dilated bronchi (bronchiectasis) from which a yellowish, thick, turbid, and glairy muco-purulent fluid was escaping. The knife, when cutting, was arrested by stony concretions which were lodged in the bronchi, and especially in one particularly dilated bronchus. This last-named bronchus contained a stone, of cylindrical shape and an irregular granular surface, surrounded by muco-pus. This stone, when washed with water, was found to be of a greenish-white colour, opaque, and measuring 4-10th inch long by 1-6th inch thick.

Five other stones were found, either more remotely situated in the same bronchus or in other neighbouring dilated bronchi. Some were small, muriform, pale green or greenish-white, and opaque; others were larger, and were elongated and irregular in shape.

Chemical analysis showed the stones to be formed of phosphate and carbonate of calcium.

The heart was voluminous, but affected with general dilatation. Another lesion was found which is exceptional in the cat, viz., the mitral valve showed lesions of chronic vegetating endocarditis, which had entailed insufficiency of the orifice. This was the cause of the hypertrophy and dilatation of the heart, which had manifested itself in the lung by the passive congestion and oedema.

The autopsy also revealed the existence of a slight ordinary ascites, the exudate of which was citrine, clear, and very fluid. The lesion was of cardio-hepatic origin. The liver was slightly atrophied, red-brown in colour, and firm in con-

sistence (cirrhosis). The hepatic veins were very apparent, showing passive congestion of cardiac origin.

The author concludes by mentioning an observation he made in the section of an aged horse. In a posterior lobe of this animal's lung, and near to the surface, he found a small smooth-walled cavity in which a calculus was lying free. This pneumolith was cylindrical in form, with short branches, was a little irregular upon its surfaces, and measured 4-5th of an inch long by ¼ inch thick.—(*Annales de Méd. Vét.*)

W. R. C.

THE BENGAL VETERINARY COLLEGE.

The following is a Government resolution (No. 2,501 Agri.) dated the 12th August, 1911, on the annual report of the Bengal Veterinary College and the Civil Veterinary Department, Bengal, for the year 1910-11.

"Colonel Raymond was Principal of the Bengal Veterinary College and Mr. Quinlan was Superintendent of the Civil Veterinary Department throughout the year. Mr. P. J. Kerr, I.C.V.D., joined for training on the 22nd January, 1911.

2. *Bengal Veterinary College.*—The number of students on the College roll at the beginning of the session was 176, but the actual number in the classes at the end of the session was 138. Of these, 38 came from Bengal, 15 from Bihar, 5 from Orissa, 67 from Eastern Bengal and Assam, and 13 from other provinces. The results of the final examination were satisfactory, the percentage of passes being 76. The conduct and general health of the students were good. The Principal reports that the students' private sick bay which was opened last year has been useful and is appreciated. A curator and librarian has been appointed for the museum attached to the college. The usual nursing class for Army Transport drivers was held during the vacation and was attended by eight men who were found competent at the end of their course.

3. *College Hospital.* During the year under report 5,869 cases were treated as compared with 5,680 during the previous year, showing an increase of 189. These figures do not include 4,000 hackney-carriage horses which were examined for the Calcutta Corporation. The number of animals sent for treatment to the college hospital in connection with cruelty cases was very small.

4. The administration of the Glanders and Farcy Act in Calcutta and its neighbourhood was conducted smoothly and efficiently under the supervision of Col. Raymond. During the year 4,025 stables containing about 16,000 horses were inspected and glanders was detected in 34 stables as against 54 in the preceding year. The total number of horses admitted into the contagious diseases hospital was 303, including 7 horses which were under observation at the close of the preceding year. Of these, 57 were destroyed, 10 died in hospital, and 230 were discharged as free from glanders, and 6 remained under observation at the close of the year. A sum of Rs. 245-5-4 was paid as compensation for the destruction of animals under the Glanders and Farcy Act in the area under the supervision of Colonel Raymond. There was no friction with the people. The management of outbreaks of all epizootic diseases, undertaken by Colonel Raymond with the sanction of the Calcutta Corporation, has borne excellent results. Special provision was made for the inspection of cattle belonging to private milk-vendors. Rinderpest was prevalent in Calcutta and the suburbs during the year; and foot-and-mouth disease appeared in several parts of Calcutta and in the Howrah and Garden Reach muni-

cipal areas. Prompt assistance was rendered in all these outbreaks. In Calcutta and the suburbs 2,276 cattle were inoculated against rinderpest.

5. *Raymond Research Laboratory.*—This institution continued to do excellent work in the diagnosis of contagious and obscure diseases in cases admitted into the hospital, and from materials sent by veterinary officers from the mufassal. The laboratory has now been fitted with an electric installation and with up-to-date instruments. Two veterinary graduates from the Civil Veterinary Department, Bengal, passed the post-graduate course of training for promotion to Inspectorships during the year.

6. *Civil Veterinary Department—Treatment of Diseases.*—Though an improvement has been noticed in some districts with regard to the promptitude with which outbreaks of disease are reported, much still remains to be done in this respect. The Lieutenant-Governor in Council notes with regret that there are complaints against the Agricultural Associations of supineness in reporting cases of outbreaks. The Inspector-General of Police has issued orders that a register of diseases is to be kept in each thana. The staff of the Veterinary Department attended 282 outbreaks in the mufassal, and performed 25,782 inoculations as compared with 12,746 during the previous year. This is satisfactory, but more can be done if the co-operation of the more enlightened members of the public is secured and the raiyats become more willing to accept this method of prevention. In North Bhagalpur, Gaya, Hooghly, Burdwan, Sonthal Parganas, Muzaffarpur and Champaran the Veterinary Assistants met with great opposition, and the fact was brought to the notice of the District Magistrate on each occasion. The efficacy, however, of preventive inoculation is beginning to be recognised.

7. *Veterinary Dispensaries.*—No new dispensary was opened during the year. One is under construction

at Bettiah, and one at Beguserai has not yet been equipped. Excluding the dispensaries at Howrah and Cooch Behar and the Pinjrapoles at Hazaribagh and Sodepur, there were 22 dispensaries under the direct supervision of the Superintendent during the year. It is proposed to close the dispensaries at Balasore, Palamau and Suri, in which very few cases are being treated. There was a slight falling-off in the total number of out-patients treated, and it is to be regretted that the raiyats have not yet learnt to appreciate the usefulness of these dispensaries.

8. *Breeding operations.*—Government does not at present possess any farms for the breeding and rearing of bulls. Two such farms are, however, maintained by the Hathwa and Bettiah Wards' Estates, which supply bulls for use in their respective areas. A herd of Siri cattle is being reared at Kalimpong by the St. Andrew's Colonial Homes with a view to improve the breed of cattle in Darjeeling. The demand for bulls for breeding purposes is on the increase, and the question has been engaging the attention of the Director of Agriculture for some time.

9. *General.*—There were 8 Inspectors and 71 Veterinary Assistants under the control of the Superintendent of the Civil Veterinary Department at the close of the year against 6 and 62 during the previous year. The scheme for the formation of a Provincial Veterinary Service was sanctioned during the year, but was not brought into operation. The local bodies concerned have been consulted by the Director of Agriculture, Bengal, and his recommendation to give effect to the scheme from the 1st April, 1911, has been accepted by Government.

10. The Lieutenant-Governor in Council congratulates Col. Raymond on another year's efficient administration and thanks him for the care and tact which he has displayed in the conduct of his duties.

Horse Breeding and Genetics.

In the Section, Agriculture, at the recent meeting of the British Association:

Mr. C. C. HURST submitted a paper on "The Application of Genetics to Horse-breeding." Soon after the discovery of Mendel's work in 1900 his attention was directed to the thoroughbred horse as a promising subject for investigation. The question of coat-colour provided a useful beginning. A few years' investigation of Wetherby's "General Stud Book" brought to light the fact that chestnut coat-colour was recessive to bay and brown. Consequently chestnut horses always bred true when mated together, notwithstanding their possible bay and brown parents and ancestors. On the other hand, bay and brown horses were of two kinds—either they threw chestnuts or they did not. Further investigation showed that grey coat-colour was dominant to bay, brown, and chestnut. Consequently every grey horse must have a grey parent and a grey ancestor in every generation in the direct line. In England grey thoroughbreds were few, and grey \times grey matings were rare; consequently English grey thoroughbreds were nearly all heterozygous, throwing bays, browns, or chestnuts. The genetic relationships between bay and brown, and between grey and roan, were not yet known. With regard to black, Prof. James Wilson had pointed out that in thoroughbreds all the so-called "blacks" were really dark browns with tan muzzles.

In the Shire and the Clydesdale, however, Professor Wilson found true blacks, which apparently behaved as dominants to chestnuts, and probably as recessives to bays, browns, and greys. With regard to chestnuts, it seemed likely that several genetic types might exist. Mr. J. B. Robertson had pointed out that the dark or liver chestnut behaved as a dominant to the light or yellow chestnut.

COAT-COLOUR AND RACING POWER.

To the practical breeder the question of coat-colour was a minor consideration, except, perhaps, in a few fancy breeds where certain colours were more popular than others. In the thoroughbred, at all events, a good horse was of any colour. A much more important question was—Can we win the Derby?

Generally speaking, coat-colour and racing power did not seem to bear any sort of relationship to one another, being apparently inherited quite independently. On the other hand, evidence was gradually accumulating which suggested that in certain strains there was a partial coupling of coat-colour and racing power. For instance, the famous St. Simon was a homozygous bay that never threw a chestnut. On the other hand, five of his most distinguished sons—Persimmon, Diamond Jubilee, Florizel II., St. Frusquin, and William III.—were all heterozygous bays and browns that threw chestnuts. These chestnut grandchildren of St. Simon had so far proved themselves to be much inferior in racing power to their bay and brown brothers and sisters. Thus, while these chestnuts had between them only won two classic races, their bay and brown brothers and sisters had between them won fifteen classic races, and were only about twice as numerous. Another interesting point under investigation was the apparent partial tripling of brown coat-colour, high racing power, and female sex in St. Simon's own offspring. St. Simon's brown fillies proved themselves to be strikingly superior in racing power to the bay fillies, the brown colts, and even to the bay colts, a few individuals of which were extraordinarily good. This was the more remarkable when we considered that in racing, colts had many advantages over fillies. It seemed possible that the elucidation of such an apparently trivial thing as coat-colour

might help to throw light on the more complicated question of the breeding of a classic winner.

HOMOZYGOUS HUNTERS.

It was generally admitted that the most useful type of light horse was the hunter. Recently Professor Cossar Ewart and he had drawn up a scheme of experiments in horse-breeding for the use of the Board of Agriculture, the object being to make a line of homozygous hunters. At present there was no such thing as a pure-breeding hunter; their studies had been mainly based on the thoroughbred chaser as probably the most suitable material upon which to work. Their investigation of the Stud Book and Racing Calendar to find suitable animals with which to experiment had led them to the discovery of the existence of homozygous 'chasers, though in very few numbers. After eliminating many hundreds of heterozygous and doubtful animals they had found five mares and three stallions, which, when bred together had given nothing but horses of the 'chaser type, as tested on the racecourse and at the stud. In view of this fortunate find of what might perhaps be called a 'chaser "pure line," they had recommended the Board of Agriculture to purchase some of the offspring of these animals, in order to increase the "pure line," and they hoped that this experiment would help them to solve the problem of the making of a homozygous hunter.—*The Times*.

Tuberculous Cattle and Compensation.

Dr. Collingridge, Medical Officer of Health, has presented to the Corporation of the City of London a report in which he analyses the final report of the Royal Commission on Tuberculosis, and points out that its findings fully justify the action taken by the Corporation from time to time on the advice of its officers. In discussing some of the administrative questions which arise, Dr. Collingridge expresses the opinion that a measure regulating the milk supply and applicable to the country as a whole is urgently required. He considers that every farmer who sells milk should be registered, that registration should only be allowed in the case of premises in good sanitary condition, and that every cow whose milk is sold should be tested by tuberculin by a veterinary surgeon. All cows found to react should be marked and registered, so that they can be followed up to the time of slaughter, and specially examined after. All cows found to be healthy should be kept absolutely apart from those reacting. No milk from any tuberculous cow (whether or no the udder be affected) should be allowed to be sold for human consumption, and if given to animals should be boiled or pasteurized before use. The machinery should be in the hands of the local authority, but ample power should be vested in the central authority to take action in case of default. All milk should be conveyed in dust-proof churns, locked or sealed and carried in properly constructed vans, and special precautions to ensure purity during distribution enforced. With regard to compensation in the case of animals apparently healthy, but found on slaughter to be diseased, Dr. Collingridge observes:

"So long as the present practice of selling to foreign countries the best of our strain which has proved to be free from tuberculosis (and foreign countries will accept no other), and retaining for the raising of our own herds at home those that react or are doubtful—so long will it be unwise to compensate. . . . Compensation should be at a fixed amount, applicable only to those animals which are clinically healthy, and no compensation should be given if it can be shown that the owner has been responsible for the disease by neglect with regard

to the breeding, feeding, or housing of the animals in question. Compensation should be given for a limited time only, say three years. During that period the farmer will be able to take reasonable steps to eradicate the disease from his herd. At the expiration of the term, the possession of a cow in a milking herd in an advanced stage of consumption should be a statutory offence."

Compensation, he thinks, if agreed to, should be paid out of national and not local funds. As regards meat, he considers that there is urgent need for a uniform standard throughout the country, binding upon all authorities, so as to abolish the absurd anomaly of meat being condemned in one locality part which is allowed to be sold in another.

VETERINARY WORK IN RUSSIA.*

By S. A. GRUENER, M.V.S., Veterinary Inspector, Kamtchatka, Russia.

We have only four Veterinary Colleges in Russia while you have nineteen such colleges in the United States. These four colleges in Russia are located at Charkov, in South Russia; Kasan, in East Russia; Jariev (formerly Dorpat), in Liveland, and Vasovie in Polen Russia.

All of these colleges were established fifty years ago, and the number of students was at that time small. For example, Dorpat, now Jariev, graduated only three students in 1880. But the growth of the number of students has been so great that now each college graduates more than one hundred each year. I have not the exact statistics of these colleges, called in Russia "Veterinary Institutes," but I can remember the data in round numbers.

College.	Number of students.	Number of graduates.
Dorpat (Jariev)	400	100
Charkov	500	120
Kasan	700	150
Varsovia	200	50
	1800	420

Statistics show that the United States has many colleges in which veterinary science is taught, but that there are comparatively few veterinary students in each college. In Russia, however, we have few colleges teaching veterinary science and a large number of veterinary students in each college. Which system, you ask, gives the better results? I answer, that I believe the system in the United States is the better, because a great many students in one college cannot get enough practical work as well as receive the proper instruction in crowded laboratories, and therefore gain only the theoretical knowledge.

The general average of students and graduates of veterinary science is greater in the United States than in Russia, and there are probably more veterinarians here than in Russia.

In comparing the course of study in Russian and American veterinary colleges we find that in Russia the course of study is longer. In the United States the students learn veterinary science in three years in the majority of colleges, and graduate as Doctor of Veterinary Science. In Russian veterinary institutes the

course of study requires four and one-half years to complete, and after passing the final examinations the students graduate only as "Veterinary Surgeons." If the students want to receive a higher degree they must take an examination again not earlier than one year after graduation and write on some topic and complete a thesis. They must defend their topic in the presence of the people, the laymen, the students and professors, "public defence." If their defence is accepted they will then receive the degree of "Magister (master) of Veterinary Sciences." The degree "Doctor" is not given to veterinarians in Russia. In other departments of the University (mathematics, language, history, zoology, botany, chemistry, etc.), the same order is maintained to receive the scientific degree. After finishing their course in the University some students take advance work, pass an examination, write on some topic and defend their work before the public. They then receive the degree of "Magister" (master) of Zoology, Chemistry, etc. To obtain the degree of Doctor, the Magister (master) must write on some chosen topic and defend it. The graduates in the medical department and medical colleges receive the degree of "Physician." If they desire a scientific degree they must take an examination again, write on some topic and defend their work. The "Physician" then receives the degree of "Doctor of Medicine" without the preceding degree of Magister (master).

In Russia you can be a Doctor of Mathematics, Astronomy, Greek, Literature and Medicine, but never of Veterinary Science. In Russia we have some veterinarians who have the degree of Doctor of Medicine, but after graduating with the degree of "veterinarians" they have enrolled in the medical department of some university and received first the degree of Physician and then that of Doctor of Medicine.

In the Russian Veterinary Institute the four-and-one-half-year course is longer than in America. It is more extensive in the natural historical sciences (Chemistry, Zoology, Comparative anatomy, Mineralogy, etc.), and has a complete course in physiology and (normal) histology. Thus we have a separate course in general pathology and a separate course in pathological anatomy taught by another Professor. We have a course in general hygiene and a separate course in zootechnics and bacteriology.

In Dorpat we have a separate course in horse-breeding. All the courses are more theoretical and on account of the large number of students in each college it is impossible to arrange for the practical work of the clinic and the laboratory.

Although the graduates of the veterinary colleges find enough employment the positions obtained are not very good, and the salaries are not sufficiently large. Many graduates continue their education in the universities and in other colleges; for example, in the medical department of the University and in the agricultural colleges. Some take special work in chemistry and receive also the degree of Doctor of Medicine, Agronomist, or Engineer Chemist. Only within recent years have the positions held by veterinarians become better owing to the success of bacteriology and the establishment of experimental stations and bacteriological laboratories. Veterinary bacteriologists can now take good positions and receive better salaries than formerly. The position of director of a veterinarian experiment station or of a bacteriologist in one is the best to be had by a veterinarian. Only after several years of practice can a veterinarian hold such a position, but students, just after graduation, are ready for several kinds of work as follows:

1. They can be employed in the Russian Imperial Army militaryas veterinarians in the cavalry, artillery, and Casakan Regiment. At present the position of the

*Abstract of paper read before the Veterinary Medical Association of the Colorado Agricultural College, April 24, 1911, Ft. Collins, Colo.

Military Veterinarian is much better than it was formerly. Now every regiment has two veterinarians, while previously there was only one. The Military Veterinarian can take a higher position in the future, as corps veterinarian and as the Head Military Veterinarian of a separate province.

2. The municipalities, large cities in Russia, employ veterinarians as Meat Inspectors and as Sanitary Veterinarian.

3. The County Board in European Russia, "Semstvo," employ veterinarians almost exclusively for the control, examination and prevention of contagious diseases. Also many counties have Veterinary Hospitals for the cure of non-contagious diseases and the care of domestic animals and live stock.

4. The Russian Imperial Government employs veterinarians on the boundaries of Turkey, Persia, and China to prevent the distribution of rinderpest.

5. The Russian Imperial Government needs many veterinarians also for the hard struggles with rinderpest which prevails in Caucasus, Turkestan and East Siberia.

6. The Russian Imperial Government needs veterinarians throughout all Russia for the inspection of cattle going from province to province or to large cities such as St. Petersburg, Charkow, Kiev, etc.

7. In Russia veterinarians are employed also in "the military guards" on the boundaries of Germany and Austro-Hungary, and China.

8. The Russian Imperial Government employs some veterinarians in the Department of Agriculture for Animal Husbandry.

9. The Department of Horse-breeding employs about two hundred veterinarians, some of which hold the position of Director of Stallion Stock.

10. The agriculture and veterinary colleges need veterinarians as inspectors and professors.

11. Russian veterinarians are employed in many places in China for the inoculation of cattle against rinderpest and for the inspection of cattle in quarantine.

12. During last year the Government of Abyssinia, Africa, asked for Russian veterinarians in place of the French veterinarians as formerly. From the above you can see that there is plenty of work to be done by Russian veterinarians. In the first place they must struggle with rinderpest, for epizootic rinderpest still exists in Russia. While it has been exterminated in almost all civilized countries in the world, it is still found in Turkey, China, and Russia. The struggle with the rinderpest requires much money and many veterinarians. However, rinderpest is exterminated in all European Russia and remains only on the borders. The chief measures against rinderpest are inoculation, preventive and curative. For preventive inoculation immune-serum and defibrinated blood taken from sick cattle is given. For curative inoculation, only serum is given.

For the preparation of immune-serum we have two experimental stations. The largest and best "antiseptic station" is located ten miles out from the city of Chita, in East Siberia. Two years ago I was employed there as assistant chief director of this station. After an absence of two years and just before coming here to the United States I visited this station and was astonished at what was accomplished in so short a time by so energetic and skilful a man as the director of this station, A. A. Dwdoo Kalof.

The station now has many beautiful buildings. It has a separate veterinary hospital, dairy farm, and three special laboratories for dairy farming; it experiments also in the raising of wild animals and the domestication of them; it has a large farm for animals for experimental purposes—rabbits, guinea pigs, arctomys; it has a special laboratory for the diagnostic investigation of glanders, and has about two hundred immune cattle,

and sent an entire carload of serum to different parts of Russia and China for the prevention of the rinderpest. This station is located on the main Siberian Railroad and many people and laymen visit it and go away very well pleased.

There is another antipestic station located at Zurnabad (Caucasus). This station investigates piropiasmosis of cattle and spirochetosis of fowls.

Unfortunately one assistant in the station, V. V. Avrorot, died from glanders inoculated by a glass test tube, containing a culture of glanders breaking and cutting his hand.

In European Russia many provinces have stations and laboratories for the preparation of anti-anthrax vaccine (Pasteur) for the diagnostic investigation and other lines of work; for example, Saratow, Samara, Simbusk, Novgorod, Voronege, Pensa Kosok, Poetava, Tovla, Oral, Ekateirnoslav, etc.

In the Cosakan province of Don there has been established a special experimental station for the investigation of glanders under the direction of Prof. Koney.

In Siberia we have a small laboratory for the investigation of the diseases of domestic animals in Tobolsk, Vladivostok. In the farthest northern point of Siberia, in the city of Jakootsk, there was recently established an experimental station for the investigation of the diseases of the domestic reindeer (*Rangifer tarandus*). The reindeer is a very valuable domestic animal in the far northern European Russia and Siberia. The life of the people of these countries is sometimes dependent upon the reindeer exclusively. In such places the reindeer is priceless as a domestic animal because they alone with the dog can endure the hardships of the icy cold, wild country. They also furnish the inhabitants of northern Russia with food, clothing, light and heat, and without them the people could not travel. Therefore the eradication of the contagious diseases of the reindeer is very important. Of the many contagious and parasitic diseases of the reindeer we know only one, anthrax. For the prevention of anthrax the Russian Imperial Government has established the experimental station for the preparation of serum and Pasteur vaccines against anthrax in the province of Afhangelsk. But the larger number of the diseases of the reindeer are not fully understood, and at present the Russian veterinarians are investigating them at the experimental stations of Ashangelsk, in northern European Russia, and of Jakootsk, in Siberia.

In the capital of Russia, St. Petersburg, we have the large main laboratory. This laboratory is situated in a new building, well equipped and costing about 200,000 roubles (\$100,000). It is divided into four departments, bacteriological, serotherapy, biological chemistry, and physiology. Eight veterinarians are permanently employed there. Every year new equipment is added to the St. Petersburg Laboratory for special advanced post-graduate courses in bacteriology and the study of the diagnostic methods.

In recent years the Russian veterinarians have published many important and interesting articles concerning investigations in bacteriology, parasitology, and serotherapy.—*American Veterinary Review*.

Medical Aphorisms.

An aphorism is described as a maxim, or a general rule. I prefer the latter definition, since in medicine very few axioms obtain. Medicine was never an exact science, and never will be, so long as the varying eddies of life and its environment are manifest. So all that a medical observer can say is that, in his experience, certain signs, symptoms and data are in the main correct; and the more observant he is, and the greater the opportunities of observation which he has enjoyed, the more likely is he to be correct in the deductions which he submits.

PTOMAINE POISONING.

By H. J. HUTCHENS, D.S.O., D.P.H. OXON., M.A.

(Continued from p. 170.)

EPIDEMICS.

If epidemics of food-poisoning be classified according to the nature of the organism concerned, they may be divided conveniently into three groups:

1. Epidemics caused by organisms belonging to the enteritidis group;
2. Epidemics due to *Bacillus botulinus*;
3. Epidemics associated with other organisms.

In the Frankenhansen epidemic Gärtner isolated from the spleen of the fatal case and also from the meat which had caused the epidemic, an organism which had not hitherto been described, and to which he gave the name *B. enteritidis*. This observation entirely altered the views then held with regard to food-poisoning, in that it showed that in some cases, at least, the disease was a true infection. In many of its characters the *B. enteritidis* (Gärtner) resembles the typhoid and colon bacilli, but shows certain differences from those organisms, and notably in its effects upon the human body. Some ten years later (1898) Durham and then de Nobelé showed that from epidemics of food-poisoning two closely related organisms had been isolated. They found that while serum obtained from any of the affected persons in a given epidemic agglutinated the organism which was the cause of the epidemic, it did not always agglutinate the bacillus from another clinically identical epidemic. This showed, therefore, that epidemics of food-poisoning might be due to either of two organisms, and that these organisms could only be distinguished from one another by resort to agglutination tests. These organisms are known respectively as *B. enteritidis* (Gärtner), which was the organism originally found, and *B. enteritidis* (Aertrycke), representing the other type, so called by an epidemic at Aertrycke in Belgium, investigated by de Nobelé.

According to Sacquépée, 80 per cent. of epidemics of food-poisoning are due to these bacilli.

The enteritidis bacilli, like the other members of the typhoid-colon group to which they belong, are short coco-bacilli, occasionally growing out into long filamentous forms, gram-negative, staining more deeply at the poles than in the centre, flagellated, motile, not liquefying gelatin and not forming spores. The group includes the various dysentery bacilli, the typhoid bacillus, the bacillus para-typhoid *a* (which causes a disease clinically indistinguishable from enteric fever) the bacilli of the enteritidis group and the numerous colon bacilli.

The various groups of intestinal bacilli can be readily differentiated by an elementary study of their biochemical reactions. The dysentery and typhoid bacilli give no gas in glucose or lactose, leave the colour of litmus milk unchanged, and form no clot. *B. para-typhoid a* gives gas in glucose, no gas in lactose, turns litmus milk permanently acid, but does not clot it. The enteritidis group gives gas in glucose, no gas in lactose, and turns milk distinctly alkaline. The colon group gives gas in glucose and in lactose, clots milk and turns it markedly acid.

Poisoning by bacilli of the enteritidis group generally takes the form of a septicæmia. The bacilli can be recovered from the blood during life and from the spleen after death. But organisms of this group give rise to a highly thermostable toxin, which will resist boiling for some little time. This is a matter of considerable practical importance, because it can be readily understood that these organisms might be present in milk, for instance, in which they would multiply and produce their toxins. If the milk were heated before being used as

food the bacilli might be destroyed, while the toxins remained, and these latter might then give rise to acute symptoms of gastro-enteritis in those who consumed it. This supposition is rendered all the more feasible by a consideration of animal experiments. Small laboratory animals fed on sterilised cultures of *B. Gärtner* or *B. Aertrycke* suffer from gastro-enteritis in the same way as though they had been fed with living cultures.

Infection with bacilli of the enteritidis group leads to the formation of agglutinins in the blood, and these are specific for the organism which was the cause of the infection. This fact is of practical importance, because in testing the blood of a person who is supposed to have suffered from food-poisoning due to organisms of this group it is obvious that blood will have to be tested as regards its agglutinating capacity, both for *B. Gärtner* and *B. Aertrycke*. It is also important to remember that co-agglutinins also appear, and unless care be taken to bear this fact in mind a Gärtner infection might be mistaken for an enteric infection when the agglutination reaction alone is relied upon, because of the considerable amount of co-agglutinin for the typhoid bacillus which is often found in a Gärtner serum.

Epidemics due to *B. Gärtner* have been recorded by Gärtner at Frankenhansen, by van Ermengen at Morseele, Brussels, and Gand, by McWeeney at Limerick, etc. In the neighbourhood of Newcastle recently, symptoms of enteritis affecting more than 100 persons were traced to the consumption of milk from a particular farm. The farm was visited, and it was found that a cow, which had recently calved, was suffering from enteritis. The cow died, and post mortem examination "revealed tuberculous pleurisy, while the kidneys and liver were completely disorganised and the fore stomach inflamed." None of the cases proved fatal. *B. Gärtner* was isolated from the stools of some of the patients, and was present in practically pure culture in the milk. Unfortunately, none of the tissues or organs of the cow could be obtained for bacteriological examination.

The *Bacillus enteritidis* (Aertrycke) has been isolated from epidemics at Aertrycke by de Nobelé, at Breslauby Kœnsche (this organism was originally described as *B. Breslaviensis*), at Düsseldorf by Trautmann, at Neunkirchen by Drigalski, etc., and it was proved to be the cause of an epidemic at Chadderton by Durham. In Newcastle in December last, twenty-one persons ate some tinned mutton; nineteen became ill with symptoms more or less severe of gastro-enteritis, and one case proved fatal. *B. Aertrycke* was isolated from the spleen and intestinal contents of the fatal case and from the mutton.

From the point of view of prophylaxis, great interest naturally attaches to the source of these organisms. So far as evidence is available it would seem that the lower animals, cattle, pigs, and horses, suffer from an acute specific infective septicæmia, accompanied by enteritis, and due to bacilli of the enteritidis group, and in the great majority of cases some history of disease in the animal whose flesh was the cause of an epidemic of food-poisoning can be obtained on careful inquiry. Van Ermengen has collected details of 112 epidemics of meat poisoning. In 103 of these epidemics the meat came from a diseased animal. In the milk epidemic already referred to, one of the cows at the farm from which the milk came was suffering from some acute disease accompanied by diarrhoea. As a rule, however, the meat has a perfectly healthy appearance, and is quite above suspicion. In van Ermengen's series, quoted above, out of the 103 epidemics in which the meat was traced to a diseased animal in only five did it show evidence of putrefactive change. Experiments have been carried out to ascertain if organisms of the enteritidis group are normally present in the healthy human and animal intestine, and some German observers have stated that these bacilli are to be found fairly frequently under such con-

ditions, Savage in a long series of careful investigations has failed altogether to confirm these results, and expresses the view that food-poisoning in man is an infection derived from animals actually suffering from disease caused by bacilli of the enteritidis group.

Organisms having the morphological and cultural characters of the enteritidis group have been obtained from numerous sources, and have received different names. In addition to the *B. enteritidis* (Gärtner) and *B. enteritidis* (Aertrycke) which have already been mentioned, the following organisms, among others, all belong to this group:—

1. An organism which had been found in association with a disease clinically resembling enteric fever in man, and known as the *bacillus paratyphoid* (beta).
2. An organism isolated from pigs suffering from hog-cholera, and known as the bacillus of hog-cholera. *B. suispestifer*, etc.

3. The *Bacillus typhimurium* (Löffler).

4. The bacillus of Danysz, found in a disease of rats.

5. *Bacillus psittacosis*, isolated by Nocard from parrots suffering from a septicemic condition, accompanied by enteritis and congestion of the internal organs.

B. Gärtner and *B. Aertrycke* cannot be distinguished on morphological or bio-chemical grounds, they can, however, be readily differentiated by agglutination reactions. Both these organisms were originally isolated from typical epidemics of food-poisoning, and have since been found in numerous similar epidemics, and neither has ever been found except in association with epidemics of food-poisoning. Clinically the symptoms produced by them are the same, and whether an epidemic is due to *B. Gärtner* or *B. Aertrycke* can only be determined by a study of the agglutination reactions of the organism isolated. From some cases, however, of disease in man clinically indistinguishable from enteric fever, an organism, *B. paratyphoid* (beta), has been isolated, which, so far as its morphological and bio-chemical reactions are concerned, is identical with *B. Aertrycke* and *B. Gärtner*.

Another important result of Bainbridge's work has been to show that the various rat viruses (*B. Danysz*, *B. typhi murium*, etc.), are bacteriologically, pure or mixed cultures of *B. Gärtner*, *B. Aertrycke*, or *B. paratyphoid* (beta). The organisms present in the different rat and mouse viruses, as well as certain other organisms, e.g. Nocard's psittacosis bacillus, had previously been regarded as closely related to Gärtner's bacillus, but their identity had not been proved. Objection has been raised to regarding the various rat and mouse viruses as identical with the food-poisoning bacilli on the ground that were they identical epidemics would have occurred among those who handled such viruses. This objection is easily met, because the handling of these viruses can be shown to have resulted in some instances in an outbreak of food-poisoning among those who handled them. In this connection the following observation of Shibayama in Japan (quoted by Sacquépée) is of interest: "In a village in the province of Tajamata a quantity of *B. typhi murium*, which was intended for use as a rat poison, was by mistake given to a horse which at the time was in perfectly sound health. The horse became ill the same day and died within a week. The carcass was buried but was subsequently dug up by a number of workmen, who ate the flesh. Within three days thirty-four of those who had eaten some of the horseflesh fell ill, and one of them died. The organism was recovered from the meat."

The so-called bacillus of hog cholera is identical with *B. Aertrycke*. This organism appears to be a secondary infection in pigs suffering from hog cholera, the true cause of the disease being one of the invisible, filtrable viruses. The identity of *B. Aertrycke* and *B. suispestifer* does not appear to be disputed, and yet very large num-

bers of carcasses of pigs which have died of hog cholera, many of them presumably being infected with *B. Aertrycke*, are annually consumed as food, and though food-poisoning is often associated with the consumption of the meat of pigs, yet the number of such epidemics is very small as compared with what might have been expected.

"BOTULISM."

Food-poisoning due to *B. botulinus* (Botulism) is a much rarer form of food-poisoning than that just considered. The symptoms are quite different from those produced by the enteritidis bacilli and chiefly affect the nervous system. The incubation period is short (12 to 24 hours) and is generally followed by some feeling of nausea, abdominal pain and constipation, but the characteristic symptoms develop later, resembling closely the symptoms due to poisoning by the vegetable alkaloids, dysphagia, dryness of the mouth, marked dilation of the pupil, paralysis of accommodation, ptosis, etc.

The disease generally lasts some weeks, but may be merely of a few hours' duration. The death-rate is high and varies from 15 to 40 per cent. of those attacked.

The symptoms of botulism are due to poisoning with the toxins of a spore-bearing bacillus, *Bacillus botulinus*, which was discovered by van Ermengen in 1895 in an epidemic of food-poisoning following a banquet at Elzevelles. The organism was isolated from the ham which gave rise to the illness, and also from the spleen and intestinal contents of one of the fatal cases. The *Bacillus botulinus* is a strict anaerobe and gives rise to an extra-cellular toxin chemically analogous to the toxins of diphtheria and tetanus. Botulism is always associated with the consumption of meat which has been preserved, and preserved under anaerobic conditions.

OTHER INFECTIONS.

Symptoms of food-poisoning sometimes follow the consumption of meat infected with organisms other than those already referred to. The nature of the infection in these cases is not definitely ascertained but would seem to be toxæmia, but whether the substance producing the symptoms is a true bacterial toxin or not is difficult to determine. Of five epidemics of food-poisoning occurring in Newcastle and the neighbourhood during the second six months of last year, three belong to this category. All of them followed the use of tinned meat. In two cases corned beef was the cause, and in one case tinned salmon.

On September 15, 1910, six persons partook of corned beef from a newly-opened 7lb. tin. A few hours (2 to 6½) later they all fell ill and the symptoms were those of a severe gastro-enteritis with collapse. The meat was bacteriologically examined and the only organism recovered was the *Staphylococcus aureus*. The meat was wet, in parts of a greenish appearance, and had a disagreeable odour. All the patients recovered. Other tins of the same brand exposed for sale in the same shop gave rise to no untoward symptoms when eaten by other customers. Ostertag refers to an epidemic of food poisoning investigated by Kuborn at Denis which was considered to be due to the *Staphylococcus aureus*.

In the other epidemic of food-poisoning following the consumption of corned beef, at least nineteen people partook of the beef and all of them suffered from a more or less severe illness. The symptoms were preceded by a short incubation period (1½ to 7 hours) and were of the nature of an acute gastro-enteritis. A proteus was isolated from the meat and was probably the cause of the illness. No deaths occurred. A portion of the meat was examined for ptomaines in London on behalf of the agents, but I am informed that no substance of that nature were present.

The third epidemic concerned five persons, a man, his wife, and his three young children, all of whom ate some

tinned salmon. One-half to three-quarters of an hour after partaking of the salmon all of them were seized with diarrhoea and vomiting and suffered from severe collapse. The woman, who was pregnant, aborted. All the patients recovered. The salmon is said to have had an "irony" taste which was so unpleasant that very little of it was eaten. The tin was sent to my laboratory, but except for a few flakes of salmon adhering to the edges it was empty. A number of these flakes were examined, and from each of them an organism absolutely indistinguishable from the *pneumococcus* was isolated in pure culture. Three other tins were bought at the same shop and the contents of all proved to be sterile.

A few epidemics of food-poisoning have been recorded in which organisms other than those mentioned above have been believed to be the cause. But enough has been said to show that while in the great majority of cases of food-poisoning the disease is due to a specific infection with organisms of the enteritis group, symptoms of gastro-enteritis, may nevertheless follow the consumption of food infected with one or other of several organisms belonging to other groups.—*The Hospital*.

Medicine as a Profession.

The choice of a profession is frequently made by a boy's father, and if he is a medical man with a good practice it has hitherto seemed only natural that he should desire his son to follow in his footsteps. It is not unreasonable, also, to assume that there is often a hereditary aptitude for medical practice, and a hereditary willingness to assume its responsibilities. For these reasons until lately a medical man in good practice almost as a matter of course brought up one of his sons to succeed him in his practice, and these hereditary followers of medicine were some of the best recruits which the profession received. We very much doubt whether this proportion of sons of medical men is now being maintained. For 20 years, during which the average number of medical students has gone down, the medical profession, especially in regard to general practice, has had to undergo many drawbacks and even hardships, and it is probable that the number of fathers, who have considered during this 20 years that in placing their children in the medical profession they were giving them the best opportunity which lay in their power of leading a useful life and securing a competence, has considerably decreased. General practitioners have seen in the many-sided development of the profession of medicine changes which necessarily have greatly affected their pecuniary returns, while they have shared in the rapidly growing expenses of daily life without in many instances being able to demand correspondingly increased fees from their clients. The decision, the very right decision, of the General Medical Council not to permit the use of unqualified assistants threw a heavy burden upon many practitioners, especially upon those who were most oppressed by the unwholesome growth of contract practice. There can be no doubt that a large number of the old-fashioned unqualified assistants were unduly employed; they were placed in positions of responsibility for which they had not received adequate training, and they gave to the public services which were not the services for which the public believed itself to be paying. While, however, the employment of unqualified assistants was abused in this manner, and, alas, in many places, the fact remains that a certain proportion of these assistants were quite properly used, while their remuneration was necessarily at a lower figure than that of assistants who, being duly qualified, had spent a large sum of money upon their medical education, the unfair growth of contract practice was directly responsible for the abuse of unqualified assistants. The public

in larger numbers, and (unfortunately) in increasingly substantial positions, began to avail itself of the contract terms which had been originally framed by the medical profession with extreme moderation, being in fact a direct outcome of the organised charity which the profession has always extended towards the public. Consequently many general practitioners found themselves confronted with the situation that part of their income was being paid to them in return for an enormous amount of work under contract that could never be remunerative—more, that could only just be made to pay when the duties were performed in a perfunctory manner and at the least possible cost. Then arose the extremely dangerous position, for medicine and for the public alike, under which thousands of persons were seen in crowded surgeries in a mechanical way, and in an incredibly short space of time, for capitation fees rarely attaining to 5s. a year and often dropping to 3d. a week. Many medical men manfully struggled in these appalling conditions to do scientific work, but some, disheartened by the conditions, discharged their responsibilities in a manner corresponding to their remuneration—they provided the kind of thing for which they were being paid. In practice of this sort the unqualified assistant was often as good a man as his principal, and when the services of persons whose names were not on the Register became illegal the troubles of the general practitioner, severe already, became accentuated, for he was not able to obtain from the various medical aid associations into whose grip he had fallen any increase of salary to compensate him for an increased outlay in the matter of professional assistance. Representations made to the medical aid associations, pointing out the abuses under which their medical officers suffered, were responded to in many cases by the introduction into the practitioners' districts of salaried medical officers to do the work of the medical aid associations, and at once the practitioners saw that, not only were their professional profits seriously diminished by the fact that persons well able to pay reasonable fees took advantage of terms of contract practice which had never been intended for them, but a grave uncertainty of tenure was introduced into professional life. A medical man could no longer bring up his son to succeed to his practice with any security, for he could no longer rely upon having a practice to which his son might succeed. In the meantime the fees for vaccination and the receipts from midwifery were decreasing for obvious reasons, while the ordinary therapeutic routine of treatment was growing more costly to him who had to supply the drugs and the dressings. All these things, acting and interacting, so altered the pecuniary position of many medical men during the last 20 years that those who have felt their full force have refrained from sending their sons to meet the same experiences. Still the supply of medical men has been kept up. The great promises of the medical life have proved sufficiently attractive to ensure able collaborators. And here we must recall the fact, often though it has been mentioned, that more than any other unit of society the members of the medical profession have inside the fence of their calling a choice of vastly varying careers. The consultant and specialist, the general practitioner, the State official, the officer, the pure pathologist—all are within our fold and have a common professional aim and code, but they lead lives that vary in every detail. Hence the medical profession has so wide an appeal that, despite the dark days through which it has recently been passing, fresh candidates for its trials and triumphs have not been wanting. We congratulate our new adjuvants upon deciding to pursue a calling that promises to all a life of the highest utility, and to some the purest possible delights through knowledge acquired and difficulties surmounted.—*The Lancet*.

A "Presidential" in Colorado.

Dr. GEO. W. DICKEY, in the course of his address at the meeting of the State Society at Fort Collins, Colorado, early in June. It is quoted here because it shows that men in the States are thinking along the same lines as some of us in Britain.

"I have no doubt that every man of any ambition has someone to whom he looks up and wishes he might become as great, as good, or as rich—that all depending upon our individual taste. Can't you remember when a boy, learning to read, you admired some one of the older boys who seemingly could do everything and did you not wish to be like him? Well, we are only learning to read in the larger sense now, for that matter, and may each one of us find some high ideal to look up to. Aspire to great things, and although you miss most of them you will still be better off for having tried. If the Governor of our great State was looking for a man to represent him at the Presidential inauguration, where would he go to look for one? Would he select one who loafed around a livery stable? Or would he choose one who has been a success in his life, either business or professional?"

You owe something to the community in which you reside. Join with the people who are boosters and help things along, not only with your money, but with some of your time. It will help you professionally to be identified with school affairs, civic societies, and some politics; for the day is coming and coming fast when we will be called upon to supervise the food supply of all the cities and towns in this nation, and we don't want the M.D.'s to have more than their just share in the work. I think we should have a member of our profession on every local board of health in the State, and when the time is ripe may we be prepared. Gentlemen, we of this State want to be in the front rank of advancement. We cannot afford to lose a chance to further our cause.

One thing I wish to compliment the members of this Society on, is the good feeling and good fellowship displayed among its members. We have no cliques nor skeletons in our closets like some other societies, and may we always be so blessed. If one of our brothers should become weak-kneed should we not furnish him with a starch bandage until such a time as he shall overcome his defect. Remember a cable is no stronger than its weakest link.

Stand together and boost. Boost for one another, boost for our profession, boost for the stock interests of the State. Show the men engaged in the stock business that their interests are our interests and will be safe in our hands. Show them that we stand at all times ready and willing to further their interests when we can do so legitimately.

Let us all become optimists. We live in the fairest State in the Union to practise in. A mile nearer heaven than those in the low altitudes. We have more sunshine and more wind, but fewer bad storms and bacteria. You ought to consider yourselves rich, heirs to the mightiest fortune in the world; manhood.

OBITUARY.

HARRY D. CHORLTON, M.R.C.V.S., Belmont, Upper Colwyn Bay. Graduated, Lond: May, 1889.

Mr. Chorlton died on Sept. 6th from melanotic sarcoma. Aged 45 years.

J. W. LITTLE, M.R.C.V.S., Abbey Town, Sillioth, Cumberland. Edin: May, 1892.

Death occurred on Sept. 8th, from chronic nephritis and cardiac failure. Aged 41 years.

Geo SMITH, v.s., Freshwater, Isle of Wight, died on Sept. 7th, from heart failure, at the age of 82 years.

Personal.

COLE.—On Sept. 13th, at Ramsgate, the wife of Mr L. Baker Cole, M.R.C.V.S., of a daughter.

The Board of Agriculture and Fisheries have appointed Messrs. George Vincent Slinn, Hedley Charles Davys Gollidge, Douglas Ainslie Hosford, Daniel Alfred Edmund Cabot to be Assistant Veterinary Inspectors (non-established) for the purposes of the Diseases of Animals Acts, 1894 to 1910; and Lewis William Wynn Lloyd, M.R.C.V.S., to be a Local Veterinary Inspector.

Messrs. NEWTON, CHAMBERS, and Co., Ltd., of Thorncliffe, Nr. Sheffield, have been awarded a Grand Prix at the Festival of the Empire for their Izal disinfectant preparations. They hold a series of highest possible awards at International exhibitions at home and abroad.

ARMY VETERINARY SERVICE.

Extract from *London Gazette*,

WAR OFFICE, WHITEHALL, Sept. 1.

REGULAR FORCES. ARMY VETERINARY CORPS.

The undermentioned Lieuts. to be Capt.—W. H. Taylor, W. N. Rowston, V. C. Leckie. Dated Sept. 1.

A CORRECTION.

The two extracts which we reprinted last week on "Bracken poisoning" and "Warbles" were from the *Annual Reports and Proceedings under the Diseases of Animals Acts* and appeared in the Chief Veterinary Officer's Report. We regret that by inadvertence they were credited to The Board of Agriculture Journal: the pages were taken out of the covers to work from, and are then similar in appearance.—H. & W. B.

CORRESPONDENCE.

THE CAUSATION OF GENERALIZED PERITONITIS.

Sir,

A question that has been exercising me a good deal of late, and on which I would like the opinion of your correspondents, is as to the possibility of the occurrence of a generalised peritonitis without puncture or gangrene of the body wall or intestines, the bursting of an abscess, or invasion via the lymph channels of the diaphragm in a case of empyema. Infection carried by entozoa or from the bladder, uterus, inguinal canal, and umbilical cord would also be, of course, excluded. Is generalized peritonitis, for instance, possible as the result of "chill"?

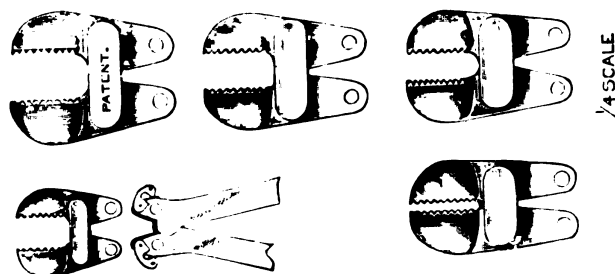

That we occasionally get a generalized peritonitis without discoverable cause is undoubted, and I would advance as a pure hypothesis, which may or may not be original, that in cases of flatulent colic with great distension of a portion of the intestine lumen, the passage of bacteria from the intestine may be rendered possible without any discoverable solution of continuity.

Capt. Vidal, R.A.M.C., has told me of a case of generalized peritonitis in a patient under his treatment preceded by flatulent colic, in which no assignable cause was discovered post-mortem. The intestinal tube was removed in its entirety from œsophagus to anus and filled with water, but no leakage could be found. The question of course is mainly of academic interest, but is in my opinion worthy of consideration.—I am, yours faithfully,

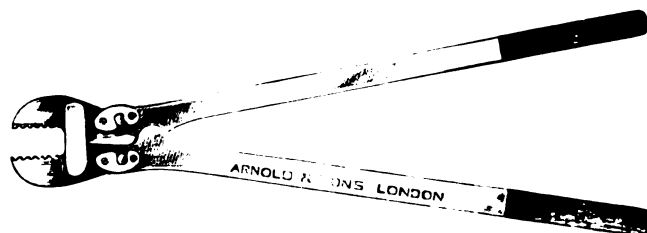

WAKEFIELD RAINBY, Capt. A.V.C.

PRACTICES FOR DISPOSAL

LONDON, W. Good-class practice returning about £800 per annum, with forge the gross returns from which are stated to be about £1000 per annum. Working expenses are exceptionally low. Convenient, well-situated house, rent £70 inclusive. Forge rent £69. Contracts produce about £300 per annum and could be greatly increased by practitioner willing to accept lower fees. Premium £1000.

WEST OF ENGLAND. Practice in good breeding and hunting district, returning £600 per annum. In present hands 10 years. Convenient house with surgery, stabling etc., rent £55. Premium one years purchase.

HEALTH RESORT. Practice returning £650 per annum, chiefly dog. Good house with large yard, stabling, kennels, etc., rent £86, or would sell freehold. Premium £750. Valuation optional.

SOUTH COAST. Country practice returning about £835 per annum, including appointments producing about £70. In present hands 24 years. The practice has been worked by an assistant who would remain if desired. Convenient house, rent £21, larger available if required. Premium £800.

IRELAND. Partner wanted to take charge of practice returning about £1200 per annum. Rent of premises £82 per annum inclusive. Contracts produce over £400 per annum. Practice has been in present hands 12 years. Premium required for half-share £500.

LONDON, N. Very old-established practice returning about £1200 per annum. Good house and thoroughly convenient premises, rent £90. The practice is principally horse. Receipts are increasing. Premium one years purchase. This practice is well-known to us and can be recommended.

LONDON, S. Practice producing over £1000 per annum. In present hands nearly 40 years. Good house, with stables, kennels, etc. rent £70. The practice is principally dog with some horses and dairies. Vendor retiring. Premium one years purchase.

SURREY. Rapidly increasing, well-established practice returning about £1000 per annum. Small house with stabling, kennels, etc. Capital required, including valuation, will be about £1300. The practice is well-known to us and can be thoroughly recommended to a suitable man.

HIGH-CLASS mixed practice returning about £650 per annum. Good premises would be let on lease or sold if preferred. Premium £600.

SEASIDE, SOUTH COAST. Partner wanted in practice returning nearly £700 per annum, and capable of great increase. Incoming partner must be good allround man. Premium for half share £300.

PRACTICES WANTED. We have several genuine purchasers on our Register whom we are unable to suit, and we should be glad if intending vendors would communicate with us as early as possible.

Royal Veterinary College, London.

(Founded 1791.)

Principal and Dean : Professor SIR JOHN M'FADYEAN, M.R.C.V.S., M.B., B.Sc.

Membership Diploma of the Royal College of Veterinary Surgeons :

Complete Courses of Instruction are conducted in all the Subjects of the Examinations for this Diploma. The facilities etc., afforded for the Practical Training of Students are unrivalled.

Bachelor of Science Degree, University of London.

The Professors of Chemistry, Biology, Anatomy, Physiology, Hygiene, and Pathology, are Recognised Teachers of the University, and conduct in their respective subjects courses which qualify for the Science Degree (B.Sc.) which may be taken concurrently with the above Diploma.

POST GRADUATE COURSES.

These Courses in Veterinary Pathology and Bacteriology are conducted under the supervision of the Principal and are specially adapted to the requirements of officers of the Army Veterinary Department, Colonial Veterinary Surgeons, Veterinary Inspectors under the Contagious Diseases of Animals Acts and Candidates for the Fellowship Diploma of the Royal College of Veterinary Surgeons.

The number of places for these Courses is limited and early application must therefore be made to prevent disappointment. The next Course will begin on Monday, October 9th, and terminate on Friday, December 1st.

The College Calendar, containing full particulars, will be forwarded on application to

The Secretary,

Royal Veterinary College, Camden Town, N.W.

THE UNIVERSITY OF LIVERPOOL

Veterinary School,

NEXT SESSION COMMENCES SEPTEMBER 28th, 1911.

Diploma of Membership of the Royal College of Veterinary Surgeons.

The Examinations for this Diploma are conducted at the University. Complete courses of instruction are given in the several subjects of these examinations, and are specially designed to meet the requirements of students preparing for the Diploma. Excellent facilities for practical hospital training are afforded in the three large hospitals attached to the School.

The University laboratories are completely equipped, and provide exceptional opportunities for the practical study of the various subjects of the curriculum.

Post-graduate Courses.

Courses in Comparative Pathology, Bacteriology, &c., are specially arranged for officers of the Army Veterinary Department, Colonial Veterinary Surgeons, and others.

D.V.H. Course. This Course taken during the Autumn and Lent terms, qualifies for the examination for the Diploma of the University.

Full particulars as to Preliminary Examinations, &c., together with prospectus, may be obtained on application to—

J. SHARE-JONES,

Secretary to the Board of Veterinary Studies,

THE VETERINARY RECORD

A Weekly Journal for the Profession.

EDITED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1211.

SEPTEMBER 23, 1911.

VOL. XXIV.

THE REGISTERED EXISTING PRACTITIONER.

A correspondent writes "Can registered practitioners use the words "veterinary surgeon" on brass plate or billheads? It was only a few years ago, when a registered man was successful in preventing the R.C.V.S. from removing his name from the list, that the position of registered practitioners under the Act became clearly understood. That position is far from satisfactory; but to enforce it strictly would be grossly unfair to the registered man.

Any man could assume the title of "veterinary surgeon" prior to the Act of 1881, which was designed to ultimately limit the title to Fellows and Members of the R.C.V.S. As in the allied cases of dentists and pharmacists, however, cognisance had to be taken of the fact that the Act, if applied universally at once, would bear hardly upon many men who had hitherto been using the title with perfect legality. Some provision had to be made for these. It was therefore decided that all unqualified men who could produce the requisite evidence of having continuously practised veterinary surgery for at least five years before the passing of the Act should, upon payment of fees, be placed upon a separate register as "Existing Practitioners." This was adequately provided for by Section 15 of the Act, which contains a sub-section stipulating that no such Registered practitioner shall be deemed to be a member of the R.C.V.S.

The men, then, proved their claims and paid their fees, believing that they were purchasing the right to work as veterinary surgeons of an inferior grade. That was the intention of the framers of the Act, but an error of omission—an evident error—rendered it nugatory. Registered men should have been exempted, as were licentiates of the Highland and Agricultural Society, from the sweeping prohibitive clauses of Section 17. They were not exempted, and the omission clearly defeats the purpose of Section 15. The only right the Registered man has under the Act is the permanent inclusion of his name in what might be made a secret list—for the Council are not obliged to publish this list of registered men, and, as the case mentioned above proved, the Council cannot remove any name from it. It was not with this idea that the registered men paid, and the Council of that day received, fees which altogether amounted to a large sum of money. The whole question is of very temporary importance, but certainly the men should rank as recognised though unqualified veterinary practitioners, and the Council should have control over them individually.

AN UNUSUAL SKIN AFFECTION IN CATTLE.

By E. WALLIS HOARE, F.R.C.V.S.

On September 2nd I was asked to investigate a peculiar skin disease affecting the limbs of a number of cattle. On attending next day I found that 15 animals were attacked.

The history was as follows: About three weeks previously a black $1\frac{1}{2}$ year old bullock was found with a swollen fore leg, the swelling being most marked in one knee joint. At the flexure of this joint deep fissures were found from which a sero-sanguineous fluid exuded. Thick crusts next formed, which gradually peeled off, leaving a raw surface with no tendency to heal.

On examining this animal I found both knees swollen, and the posterior aspect of one knee especially showed deep fissures and an appearance as if a strong biniodide of mercury blister had been applied to the part. The scaly condition also extended to the metacarpal region.

On examining the other cattle, various stages of the skin affection could be observed on them. The majority of the animals were two-year-old bullocks in prime condition, a few were three-year-olds.

The first symptom to attract attention was a swollen condition of the knees; in some of the cases careful examination showed the presence of a number of small sized pustules with a hard base and deep-seated. This was evidently the first stage. In others, the skin lesions were exactly similar to what is known as "mallenders" in horses.

Many of the cases showed deep-seated ulcers, evidently the result of the animals constantly licking the parts.

In only a few of the cases were the hind limbs involved, and the lesions in this region were slight. Some of the animals developed abscesses at the back of the knee and in front of the shoulder, evidently due to a secondary infection.

The course of the disease is slow, as the first animal attacked still shows swollen knees and a scaly condition of the posterior aspect of these joints. The herd consisted of 28 animals, and of these 26 are now affected; by a strange coincidence the two that escaped suffered for some time from a mild attack of ringworm.

Two milch cows were attacked, while a mare and a donkey showed the typical skin affection at the back of the knees, the mare also developed the affection behind the elbow.

Although in some of the cases progression was painful, the animals did not lose condition, and constitutional disturbance was absent. In some instances an entire fore leg was swollen, and the

scaly condition of the skin extended to the fetlock. In others various parts of the body showed slight lesions. In every case the primary seat of the disease was at the posterior aspect of the knee.

Some of the animals seemed to suffer from a very mild attack, and recovered in a short period of time. Others appeared to be infected with a very virulent type of the disease, as the swelling of the limb was extensive, and the ulcerations very deep seated and showed no tendency to heal.

As regards the etiology, nothing could be discovered. The pasture is good; the water supply is from a river. Into this river the affluent from a creamery flows at a little distance up the stream. The cattle during the hot weather used to stand in this stream for several hours daily. But this affluent has flowed into the stream for several years without causing any apparent damage to cattle; moreover the milch cows had not access to this stream.

The disease has spread to a cow and some young cattle on a neighbouring demesne, although there was no contact between these animals and the affected ones. Enquiry has elicited the fact that further outbreaks have occurred on farms at a distance from the primary outbreak. In various parts of the country I have found on enquiry from practitioners that similar cases have occurred, but only in a small number of animals. So far as I am aware at present, the disease has only appeared in enzootic form in the Muskerry district.

On looking up the literature of skin diseases, the only affection that corresponds to the present outbreak is "eczema of the limbs" in cattle, described by Moussu and Dollar, and said to be due to feeding on malt and potatoes. These factors are absent in the present instance.

Impetigo in cattle, described by Cadéac, also bears some points of resemblance to the cases I mention.

Why the disease should chiefly affect the posterior aspect of the knees is a point that needs elucidation, also why the fore limbs are especially the seat of the disease. I should gladly welcome any information as to the nature of the disease, probably there are practitioners who have met with similar outbreaks. Up to the present I must confess that it has completely puzzled me. (See postscript, p. 200)

TWO CASES OF SUB-SACRAL ABSCESS.

On reading a case of sub-lumbar abscess in *The Record* of 9th inst. which unfortunately ended in death, I thought the following cases might be of interest. I note the case reported was in a grey horse, the following subjects were also grey horses.

Case I. Grey gelding, age six years, was admitted to infirmary September last year, had been on military manoeuvres and was returned having his tail slightly thickened and showing several small abscesses on the under surface. He had been docked, but not recently, the stump of the tail appeared healthy, there were also two small abscesses at the root of the tail, one on each side of the anus. These were opened and discharged a thick

creamy pus which was suspicious of the botriomyces. Treatment consisted of thoroughly disinfecting the tail, the abscesses being injected with Tinct. iodine, and Pot. iodide given internally. The tail, however, began to enlarge and the pus to increase in quantity, especially in the perineal region; the animal began to show signs of systemic disturbance, the temperature began to rise and the animal's appetite was decreasing. As the source of the infection appeared to be the tail I decided to amputate it. The animal was deeply chloroformed and the tail removed as close to sacrum as possible. The stump was well syringed out with iodine on the under surface of the bone, this being the tract of infection. The amputated tail was found to be full of sinuses, pus was present in great quantity between the skin and the under surface of the vertebræ. The animal made an uninterrupted recovery after being under treatment for about six weeks.

Case II. A grey van gelding, age five years, admitted to infirmary February this year. This animal when admitted did not show any abscesses in the region of the root of the tail, but the middle of the tail was badly bruised; the dealer had evidently fastened another horse to it by means of a rope, and this was undoubtedly the cause of the infection. In a few days the tail began to swell, several incisions were made in the tail and a considerable quantity of thick pus let out. Owing to the considerable depreciation in value that would take place on amputation of the tail, I decided to leave that as my last resource. Numerous abscesses appeared on the under surface of the tail and the tendency to spread was always in an upward direction; very soon pus appeared at sides of anus and above the root of tail; by inserting the finger in one of these at side of anus, pus could be also evacuated from under the sacrum. Although iodine was fully used, we seemed quite unable to prevent fresh abscesses forming in the perineal region. Amputation was then resorted to; some difficulty occurred in checking the hæmorrhage, but apart from this the animal began to improve daily. It was under treatment for about seven weeks.

Peckham, S E.

H. D. JONES, M.R.C.V.S.

DIGESTIVE TROUBLES OF THE OX.

By JAMES GREGG, Belfast.

I am delighted to see something original on this vexed question. The article from the pen of my at one time fellow student, Mr. Hugh Begg, is worthy of him, and of the profession of which he is an active member. Mr. Begg was looked up to by his fellows in the old days, as a man of promise, and I am sure that all those who were then associated with him, now scattered over the world, will say with me that the article referred to is the best original contribution on the subject, and that our prognosis has been fully justified.

My own observations have led me to place the ordinary digestive troubles of the ox under two headings.

- (1) Those due to chills.
- (2) Those due to errors of diet.

The first is perhaps not so common in the neighbourhood of cities owing to better care and better housing of milk cattle. If these so-called chills cause a rush of blood from the superficial vessels to those of the internal organs—we may take it that continuance for a short time will produce congestion, which may go the length of producing pain and inconvenience owing to pressure (such as occurs in rheumatism.)

Different modes of treatment, to a certain extent, prove this theory to be correct. Large doses of salts usually make the animal worse, *i.e.* increase the irritation and probably cause the congestion to end in inflammation of the abomasum or some other organ—whereas prompt bleeding and the administration of heating carminatives give relief in a few hours.

In looking back to my boyhood days, I can remember a handy man who could always cure such cases without any bad after effects. He bled and gave "the five ounces," *viz.*, ginger, pepper, saltpetre, cream of tartar and sulphur. During the earlier years of my professional life I did not bleed, and I did not use such simple remedies: the result was that I was frequently disappointed. It was not until I arrived at years of discretion that I would deign to copy the handy man.

The second class is very common in the neighbourhood of cities, where forced feeding is the order of the day. It may be at once conceded that fluids pass from the rumen to the abomasum whether cud-ding goes on or not, therefore when the former is filled with highly concentrated nitrogenous food, which, owing to its sour flavour or other cause, the cow ceases to lift for re-chewing, it is reasonable to suppose that the stasis causes poisons to be generated, which have a serious effect on the nervous system. We know that the stomachs become paralysed, and that not infrequently the animal becomes helpless, and is unable to rise. Grass staggers, due to eating the nitrogenous blossoms, is an example of the same thing, though it has another set of symptoms. Purgatives, especially salts, in such cases increase the depression and hasten death. I find the following, drenched every three hours for six times, to act better than any other which has come my way:

R	Zing. Pulv.	} aa. ʒii.
	Sinapsis	
	Sodii. Chlor.	
	Sodæ. Bicarb.	
	Ac. Carbolie	} aa. ʒi.
	Cayenne	

No food, but water *ad lib.*

After making numerous post-mortems on all classes of cattle, I have long since thought so-called impaction of the third stomach a myth, and accordingly have set to myself the task of finding something harmless to neutralise the ferments which are undoubtedly generated during derangement of the digestive mechanism, as I am firmly convinced, and have ample evidence to prove, that no treatment at all is far preferable to treatment along recognised lines.

ABSTRACTS FROM FOREIGN JOURNALS.

QUARTER-ILL IN THE HORSE.

H. Levens, of Goch, who recently recorded a case of equine quarter-ill (see *Veterinary Record* of June 24th, 1911, p. 802) now reports another.

The subject was a very valuable Belgian pedigree mare, about three and a half years old. One morning this mare appeared ill after having been upon the meadow the day before in good health and spirits. Despite this she was taken to work, and an hour later she began to go lame. She had scarcely been unharnessed on this account when she fell several times, but each time was able to rise again unassisted. When Levens saw her she had become worse, and he describes her condition as follows.

She was lying upon her side, and was completely covered with sweat. She attempted to rise, but in vain, the hind quarters being completely paralysed. There was clearly recognisable emphysematous swelling in the region of the loins and croup, and the lightest pressure upon this caused the animal great pain. The tongue was cyanotic, and hung sideways from the mouth. The eyes were staring and the conjunctivæ were dark-red, almost blue. Some blood had flowed from the vagina, but the urine was clear.

The respiration was groaning, and 60 to 70 per minute; pulse 80 per minute, very weak, and occasionally intermittent; rectal temperature 105.8 F. The appetite was completely suppressed, water only being taken in small quantities.

Levens mentions the possible suspicion of azoturia in order to demonstrate its untenability. The loss of blood from the vagina, the cutaneous emphysema, the high temperature, and the cyanotic tint of the mouth and conjunctivæ were not symptoms of azoturia, but pointed to the existence of a severe infectious disease. This, Levens considered, must be quarter-ill, and he therefore diagnosed the case as such during life. Twelve hours later the mare was dead, one final symptom being a discharge of blood from both nostrils.

The diagnosis of quarter-ill was fully confirmed by an independent official investigation. The most marked post-mortem feature, besides general muscular anæmia, was the pronounced bloody infiltration of the subcutis, which, upon microscopical examination, was found to contain indisputable quarter-ill bacilli.

Quarter-ill is fairly common in Levens' district, especially in one particular portion of it, where, during the five weeks previous to writing the present report, he has encountered six cases. Four of these were in cattle and two in horses, and in each case the animal had either been pastured upon a particular infective strip of meadow land or been fed upon hay derived from it.—*Berl. Tier. Woch.*

(This case, though not so fully reported, is evidently very similar to the previous one described by the same author.—TRANSL.).

HEPATIC ABSCESS OPENING INTO THE POSTERIOR VENA CAVA.

Lhoste records (*Revue Vétérinaire*) the case of a Gascon ox which, for two years past, had shown vague symptoms of illness, the cause of which could not be diagnosed. The tuberculin test gave a negative result. The animal died very suddenly; and, as anthrax was suspected, a post-mortem examination was made with the following result.

The liver was considerably enlarged and degenerated. Its centre showed a voluminous, soft, fluctuating tumour which, when incised, gave exit to a litre (=about 1½ pints) of pus. The wall of the abscess was constituted by Glisson's capsule, which was sclerosed. At the point where the purulent collection was in contact with the vena cava, the wall of the latter was extremely thinned and presented an ulceration, the evolution of which had caused the almost complete perforation of the vessel. When the interior of the vein was examined, it was possible to demonstrate that its walls were covered by a purulent layer having the same characters as the pus in the hepatic abscess. Finally, the right auricle and a portion of the right ventricle were filled by a purulent liquid, which was also found in the axillary vein.—(*Annales de Méd. Vét.*)

"COLD ABSCESSSES" OF BONES—TWO CASES.

Cabayé records (*Revue Vétérinaire*) two noteworthy cases under this heading.

The first was in a spaniel, which showed a marked lameness of the right fore limb. Upon examination a diffuse, sensitive, warm tumefaction was found, and this being attributed to rheumatism, the animal was treated with sodium salicylate and external applications of tincture of iodine.

The treatment was without effect, and a month afterwards the animal was unable to bear weight upon the limb. Palpation revealed an osseous hypertrophy of the scapular fossæ, and pain, accompanied by a warm tumefaction, under the shoulder. A subscapular abscess was suspected, but a puncture with the trocar gave a negative result.

The animal was killed, and it was found post-mortem that the external aspect of the scapula showed a hypertrophying periosteitis, which filled the supraspinal and infraspinal fossæ. The subscapular fossa was uniformly covered with osteophytes, but here the hypertrophy was only apparent, for it was reduced to a simple osseous lamella bounding an anfractuous cavity filled with pus.

The second case was also of a dog, which received a violent contusion in the region of the left arm. All treatment was unsuccessful. The animal showed a tumefaction involving the left humerus and especially marked about the upper third of the bone. This dog, like the first, was destroyed and subjected to post-mortem examination.

This revealed the connective tissue thickened over the whole extent of the limb. The muscles of the arm were sclerosed, and their connective tissue

covering formed the anterior wall of a vast abscess which was limited posteriorly by the humerus. When this abscess was incised it was found that the purulent collection communicated with the medullary canal of the humerus by two fistulæ. The bone itself was the seat of a hypertrophying periosteitis, the osseous productions of which were about four-fifths of an inch thick.

In both cases the author explains the genesis of the abscesses as follows: In consequence of a traumatism, a hæmatoma had formed between the bone and the muscles, and this had become transformed into an abscess as a result of an endogenous infection.—*Annales de Méd. Vét.*

OFFICERS TRAINING CORPS.

DUBLIN ROYAL VETERINARY COLLEGE CONTINGENT.

Following the organisation of contingents of the Officers' Training Corps at the different Universities and Medical Schools, a contingent in connection with the Royal Veterinary College of Ireland was established during the past Session.

The first parade was taken by General Sir Neville Lyttelton, General Officer Commanding in Chief the Forces in Ireland, on May 4th, 1911, some sixty cadets being present.

During the summer term parade and other drills were held, and occasionally the contingent attended the Marlboro' Barracks for instruction in the Veterinary Hospital.

After the professional examinations were over the contingent proceeded to the Curragh Camp for a fortnight's training. The contingent brigaded with the College of Surgeons Officers Training Corps in Donnelly's Hollow, being under canvas all the time.

At the Curragh full advantage was taken of the Veterinary Hospitals, and lectures were also given upon the equipment of the veterinary hospitals in the field and the duties of the veterinary officer on the march and on active service. The Contingent also, by the kindness of the General Officer Commanding the 5th Division, on two days had mounted drill. The work during Camp was briefly as follows:

Reveille at 5 a.m.; parade for drill at 6 a.m.; breakfast 7.30 a.m.; camp inspection at 9 a.m.; parade at 9.30 a.m. and march to veterinary hospital; dinner at 1 p.m. Afternoon parades for drill, tent-pitching, etc. Lights out 10.15 p.m.

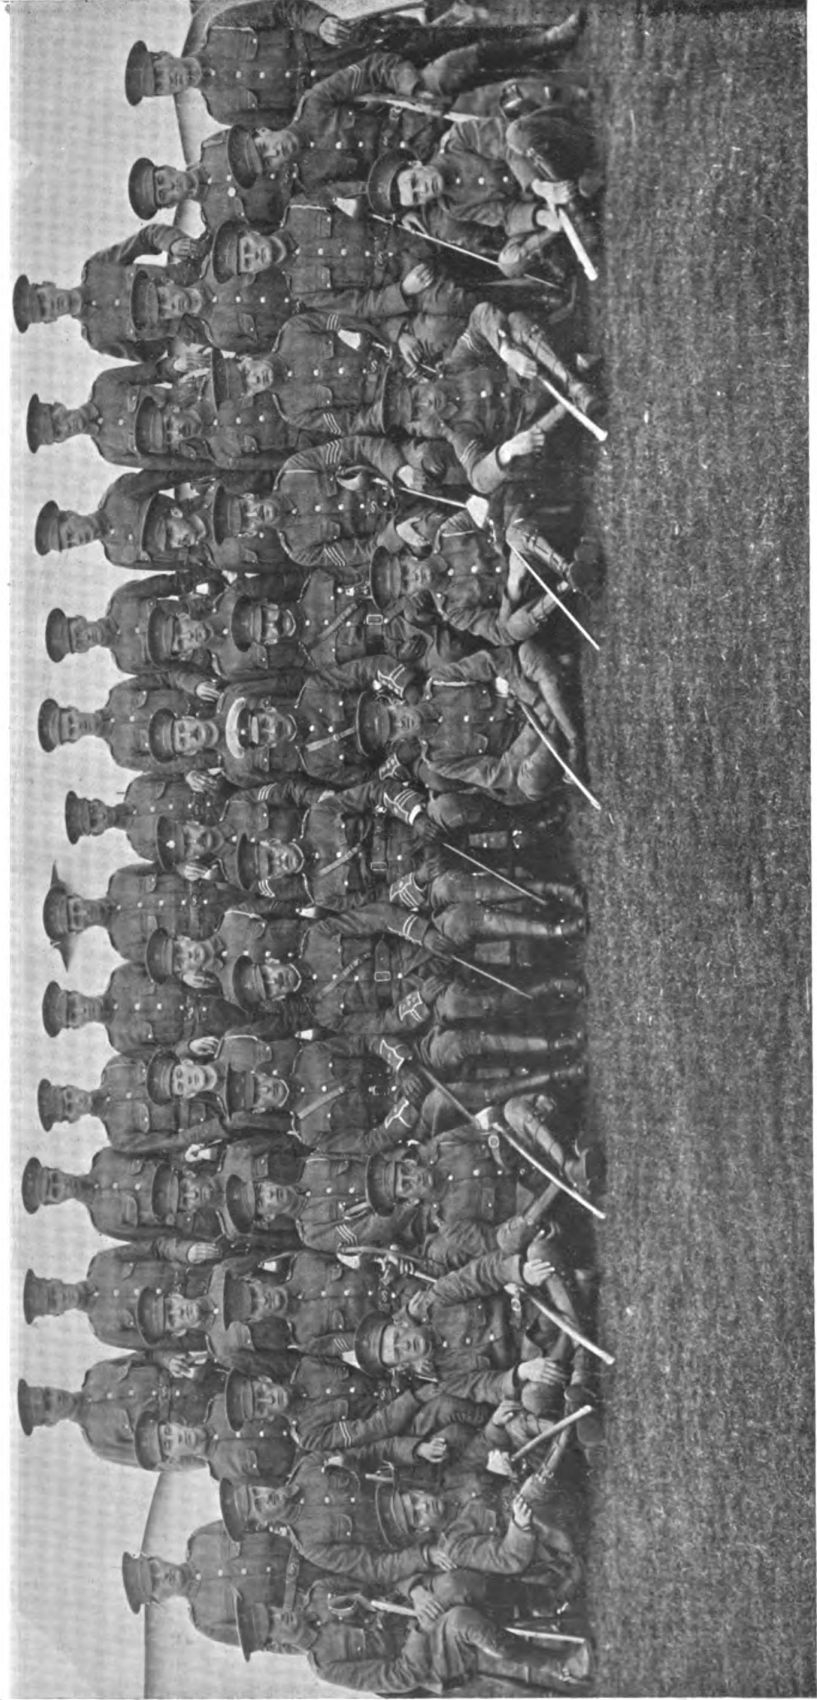

During the training the contingent was inspected by the Director-General of the Army Veterinary Service (General Pringle, C.B.); the Principal Veterinary Officer Irish Command (Lt.-Col. J. Moore), and also by Genl. Sir Neville Lyttelton, K.C.B., the General Commanding in Chief, the Forces in Ireland.

Although the contingent has been only recently formed it has created a good impression. The cadets have shown themselves very apt and keen in their work and present a good appearance on parade. The strength of the contingent it is expected will be greatly increased during the next session. The War Office has sanctioned the appointment of a Sergeant-Instructor from the Army Veterinary Corps, and it is intended that the contingent at present armed with swords will in addition receive revolvers. At present the strength of the contingent, which is officered by the staff of the College, is five officers and 50 cadets, including a staff sergeant, and four sergeants, all cadets. The officer commanding the contingent with the rank of Major is Prof. Mettam, the Principal of the College.

June
p. 18

EASTERN COUNTIES V.M.S. AT YARMOUTH, SEPT. 7TH, 1911, MR. T. G. HEATLEY, President.

OFFICERS' TRAINING CORPS, ROYAL VETERINARY COLLEGE OF IRELAND CONTINGENT.

It should be mentioned that during the recent Royal visit to Dublin, the contingent assisted in lining the streets with the Dublin University and Royal College of Surgeons Contingents Officers Training Corps, and at the Royal Review the contingent was included with the above contingents and that from the Queen's University of Belfast, in the command of the Earl of Arran, K.P. The contingent was also represented at the Windsor Review.

It may be stated that the Officers Training Corps is open to all students, and entrance into the Corps carries no obligation to enter the Regular Army. The object is to provide material for the Reserve of Officers and give training which may be of service in case of need. In the Universities there may be contingents of (a) Infantry; (b) Artillery; (c) Cavalry; (d) Engineers; (e) Medical, in connection with the Royal Army Medical Corps. The Veterinary contingent, as furnished by the students of the Royal Veterinary College of Ireland, takes its lines from the Army Veterinary Corps. Its relationship to the A.V.C. being the same as the Medical contingents to the R.A.M.C.

In future, to create a spirit of emulation between the different sections of the contingent, an intersectional challenge cup, generously promised by Mr. Charles Allen, F.R.C.V.S., will be offered for competition, the details of which have yet to be settled.

EASTERN COUNTIES VETERINARY MEDICAL SOCIETY.

A meeting was held on Thursday, Sept. 7th, at the Royal Assembly Rooms, Great Yarmouth. The members and their wives were first entertained to luncheon as the guests of the President, Mr. T. G. Heatley, of Woodbridge. A group photograph was taken, after which the business meeting was held. Among those present were Messrs. W. Hunting, J. E. Kitchen, London; F. L. Gooch, Stamford; H. E. Wilkinson, Martham; J. R. Hewer, T. E. Auger, Wymondham; B. W. Bloomfield, Walton; W. Waters, Blofield; J. Barr, Acle; F. B. O. Taylor, Weston; H. P. Standley; R. B. Palmer, H. Buckingham, Norwich; W. Shipley, W. L. Little, Yarmouth; W. M. Reeman, Bury St. Edmunds; E. Margaron, Swaffham; S. Smith, senr., S. Smith, junr., Hon. Sec., Lowestoft; J. F. Thurston, Fressingfield; A. Holt, New Buckenham; J. K. Gooch, Holt; D. S. Jack, King's Lynn; J. R. Godbold, Stowmarket; E. H. Leach, Newmarket; E. W. Wright, Yoxford; M. Bray, Docking; and W. Turtill, Wickham Market.

Visitors: Messrs. F. Chambers, R. E. Leach, and H. Gooch.

Letters regretting inability to attend were received from Sir John McFadyean, Messrs. N. Almond, A. H. Santy, W. N. Jurgensen, T. E. Barcham, A. Burgon, W. E. Livock, F. Morton Wallis, J. Hammond, Senr., H. F. Downe, J. Bee, W. W. Kerr, E. A. Hudson, J. Cleveland, and W. Bower.

The minutes of the last meeting at Bury St. Edmunds were adopted, on the proposal of Mr. Sidney Smith, senr., seconded by Mr. A. Holl.

Mr. A. McTurk, Swaffham, nominated at the last meeting, was elected a member on the proposition of the President, seconded by the Hon. Sec.

The Hon. Sec. said it was reprehensible that six of the members failed to reply on the postcards he sent out asking whether they would attend. It was the more to be regretted because the President had invited them to lunch. It would greatly facilitate matters, too, if members would reply earlier. Up to Monday he had not received more than half the replies.

KIRK APPEAL FUND.

The Editor of *The Veterinary News* wrote asking whether the members would contribute to the fund he is organising to assist Mr. W. Kirk in the appeal entered by the London County Council to compel veterinary surgeons to pay for the use of the College arms.

Mr. W. HUNTING, called upon by the President, said he rose in accordance with his request, but personally he was not an admirer of practitioner's use of the College arms. Although it was very commonly done, he did not think it showed very elevated taste to have one's letter paper decorated with a number of crests. But in a case where one of their members had been attacked and had the pluck to defend himself, he thought it would be rather mean to leave him to do so alone. He had already subscribed to the fund with the Central Veterinary Society. He hoped veterinary surgeons as individuals would support Mr. Woodruff in his object.

Mr. SHIPLEY said that as a matter of principle he thought it very bad form indeed to use the College arms though he realised that Mr. Kirk might be in a difficult position. If veterinary surgeons wanted to use crests of any kind in their business or for their private purposes they should have their own and pay for them. It was a matter in which personally he took very little interest.

Mr. H. BUCKINGHAM, as a veterinary surgeon who used the College crest, said he saw no reason why they should not use it. It distinguished them from the quacks. It had been used for many years, but independently of that, one of their fellow-practitioners having got into this fix, they ought one and all to help him. One member should not have to bear the whole brunt, and they could conscientiously give their mite towards it. He therefore advocated a contribution from the Society.

The PRESIDENT said he thought it was purely a question for the individual whether he thought this action right. He did not see how they could ask the Society to do anything, but they could give as individuals. If a man had a strong feeling on the subject he should subscribe.

Mr. BUCKINGHAM said he would test the feeling of the members by proposing that the Society contribute two guineas.

There being no seconder, this proposal fell to the ground, and no action was taken.

NATIONAL VETERINARY ASSOCIATION.

A letter was read from Mr. A. Gofton (Edinburgh) as to the amendment of the rules of the National Association. The President said that at their last meeting they had approved the scheme, and he therefore proposed that their Society affiliate with the National.

Mr. T. E. AUGER seconded, and this was carried.

The Hon. Sec. called attention to the list of instruments printed on the agenda papers for the information of members. The tooth clippers and forceps had been most in demand. Some of the instruments needed repair, and he asked for instructions.

Mr. W. SHIPLEY said this should be left to the Committee with power to order any repairs. He moved accordingly.

The PRESIDENT seconded, and this was carried.

Mr. SHIPLEY proposed that the annual meeting be held at Norwich.

Mr. SYDNEY SMITH, SEN., seconded, and this was carried.

MILK FEVER.

The PRESIDENT said he would like to mention as a point of interest to anyone working out the etiology of milk fever, that while in 1908, 1909, and 1910 during the months of June, July, and August he averaged 39 cases

of milk fever, this year, he had only had one case. The past three summers were wet and this year dry, and he wondered if other members had had the same experience. It showed that hot weather was not a producing cause.

Mr. W. L. LITTLE said he thought it depended upon the quantity of grass.

The PRESIDENT, in reply to a question, said the herds would average 30 cows.

Mr. WRIGHT said he had had just as many cases, and he found the number to be the same in hot weather as in cold. He had some quite lately.

Mr. WILKINSON said he had a herd of 40 Jerseys, and during the past two years had cleared out all the tuberculous cows. This summer there had not been one case of milk fever. Previously it used to occur constantly. The cows were calving all the year round.

Mr. HOLL said he had three dairies of between 50 and 60 cows, and he used to have 15 or 16 cases each year, but this year there had been only one case in the three herds. There had been this year nothing like the milk fever in Norfolk that they used to have.

Mr. BLOOMSFIELD said that in his district there were a few cases in June and none since.

Mr. T. E. AUGER said his experience was the same as the President's and he had had very few cases indeed.

The PRESIDENT said there was certainly a weight of evidence that there was very little milk fever this summer, and the reason must be the great scarcity of grass feed.

POST-MORTEM SPECIMEN.

Mr. F. B. O. TAYLOR exhibited a calculus taken from a carriage horse. He got a wire to take a calculus from the urethra of a horse, and also to bring his gun. He found the calculus lodged in the perineal region, where it could easily be felt. He was asked to take it away immediately or shoot the horse. As the horse was 20 years old and had had paralysis of the neck of the bladder for 18 months and was practically useless for driving, he said the best thing was to shoot it. Prof. Hobday had taken one calculus out of its bladder, and the late Mr. Fred. Low had taken another from its urethra. The present calculus was just below the anus. There was a good deal of urethritis, so that if the horse had been operated upon it would not have been much good.

The PRESIDENT said the calculus was a very pretty specimen, and it was an interesting case. There must have been considerable dilatation of the urethra for it to have got into the perineal region.

THE OUTLINES OF VACCINE AND SERUM THERAPY AS APPLIED IN VETERINARY PRACTICE.

By A. L. SHEATHER, M.R.C.V.S., London.

Mr. President and Gentlemen,—When, in the early part of this year, I received an invitation from one of your members to read a paper before this Society upon vaccine and serum therapy, I must admit that the difficulties which the subject presented seemed almost insurmountable. It was not a case of finding sufficient to say but one of deciding what not to say. A few moments consideration convinced me that only the very sketchiest of outlines could be given if a comprehensive survey of the subject were to be attempted, and that debatable points and theories must be left severely alone.

I have therefore confined myself to a few considerations of a general nature regarding the various types of immunity, and to a brief description of some of the measures adopted in the production of it, making such choice as may illustrate as many as possible of the various principles involved.

In nature such a thing as absolute immunity is quite exceptional. By absolute immunity is meant such a degree of resistance that an animal cannot be infected with a particular disease under any circumstances whatever. When, therefore, one speaks of an animal being immune to a particular disease one generally means that it is capable of resisting any infection that it may meet under natural conditions. Immunity is therefore relative only in the great majority of cases. There are numerous examples of animals that one would speak of as being immune, but which can be infected experimentally. Such a case is the horse, which though never naturally attacked with swine erysipelas may be experimentally infected.

Classifying immunity upon the broadest basis possible, one may divide it into two great types—natural and acquired.

Natural immunity I have just referred to. It may be defined as an inherent insusceptibility on the part of an animal to a particular disease under natural circumstances. Since neither sera nor vaccines play any part in its production we may dismiss it.

Acquired immunity. This immunity is not all of one kind, and further sub-division is necessary. (I.) First there is such a thing as acquired natural immunity, by which I mean an insusceptibility on the part of an animal towards a particular disease which is possessed by that animal for a part of its life only, the immunity being acquired without the necessity either of the animal passing successfully through a natural attack, or of its being treated in any way by man. As such an immunity I may instance the case of black-quarter in bovines. It is well known that this disease is very fatal to young stock, but that cases are fewer among animals of 1½-2 years of age, and that they are distinctly rare in animals over three years of age. No definite explanation can be given to account for this immunity, though more than one theory has been advanced.

II. The second type of acquired immunity is that which an animal possesses by virtue of its having passed through a natural attack of the disease in question. Examples of this are numerous. There is one example of immunity acquired in a manner that is a modification of this which is perhaps worthy of mention. I refer to the immunity that is in some cases produced in young animals owing to the mother passing through an attack of the disease while pregnant. Such a case is that of Malta fever. The goat is particularly susceptible to Malta fever, but it has been found that the progeny of infected females possess a high degree of immunity, although they have never actually had the disease.

(III.) The third type of acquired immunity is that which results from man's intervention. Here again the immunity is not all of one kind.

Two separate and distinct types of immunity may be conferred upon animals by man. Special names have been given to these types. They are known as active and passive immunity. Generally speaking, active immunity is that which is produced by vaccines, or in some cases vaccines associated with protective sera, and passive immunity results from the use of sera alone. The main idea of vaccination is to imitate nature in producing immunity by causing the animal to pass through an attack of the disease in question, but to modify nature's methods in such ways that a greater degree of safety may be obtained without sacrificing the strength of the immunity.

The special features of active immunity are as follows. The essence of the immunity is that it results from a reaction on the part of the animal's own tissues, the immunity being, broadly speaking, proportional to the reaction. In other words, the animal prepares its own protective substances, whatever they may be. The second characteristic is a natural corollary to this, and it is that some time must always elapse before the

immunity reaches its maximum. That is to say, no animal is ever immune immediately after a vaccine has been administered. Thirdly, the immunity, once established, is lasting. In some cases the immunity may last for years. In others it is a matter of months. Finally, although in devising methods of vaccination every effort is made to secure safety without sacrificing effectiveness, there must, in the nature of things, always be some risk to the animal vaccinated.

Although I intend to deal with active immunity before passing on to passive immunity, I think it well to give here for the sake of contrast the principal features that characterise passive immunity. As I have already mentioned, passive immunity is set up by the use of protective sera, and herein lies the explanation of the principal features exhibited by such immunity.

First, the immunity resulting from the use of a protective serum is set up without any reaction on the part of the tissues of the animal protected. The protective materials are actually present in the dose of serum administered, the animal being simply a passive receiver.

The second feature is that, as one would naturally expect, immunity is conferred at once. That is to say, from the moment the animal receives the dose of serum it is protected.

Thirdly, the immunity established is comparatively fleeting. It commences to decline from the outset and has generally entirely disappeared within a few weeks, and in some instances ceases even to be serviceable after a matter of days.

The fourth characteristic is that the production of passive immunity in an animal is without danger. This statement, in view of more recent work, is perhaps a little too positive. I will indicate later circumstances under which danger may arise.

ACTIVE IMMUNITY.

I will now deal briefly with the methods adopted in the production of active immunity. As I have already stated, in the production of active immunity an attempt is made to imitate nature while lessening its risks. For this reason various modifications of the natural virus have been resorted to in the preparation of the vaccines. The following are the principal modifications of the natural virus that are resorted to in the preparation of vaccines:

1. The fully virulent virus administered in minimal doses.
2. The administration of the virus deprived of some of its virulence.
3. The administration of dead virus.
4. The administration of bacterial products.
5. The administration of either fully virulent or attenuated virus associated with a protective serum.

The administration of fully virulent virus in minimal doses.

An example of this method of vaccinating is that devised by the late Prof. Arloing in conjunction with Cornevin for the protection of animals against black-quarter or quarter-ill.

The method of preparation of the vaccines, for there are two, known as 1st and 2nd, is as follows: A sheep is killed experimentally with black-quarter. Immediately after its death the muscular lesion is exposed, all precautions being taken to prevent accidental contamination and the affected muscles are cut out. These are then cut into strips about three inches long and one wide, and dried at a temperature below that of the body until they become quite brittle and can be broken in the fingers. In this condition the muscle may be kept for an almost indefinite period.

The pieces of muscle are then ground up in a sterile mill and reduced to powder. This powder is mixed

with sterile water until it has the consistency of a stiff paste. The paste so prepared is spread out in layers about $\frac{1}{4}$ inch thick upon glass plates which are then heated. The temperature to which the plates are raised depends upon whether one is preparing the 1st or weaker vaccine, or the 2nd.

For the first vaccine the temperature must not be allowed to fall below 100° C., and for the 2nd vaccine it must not fall below 90° C. In both cases the paste is submitted to this temperature for seven hours. At the end of this time the paste is found to have been converted into a hard cake or crust. This cake is again reduced to a powder by grinding in a mill. The resulting powder is the vaccine.

It was at one time supposed that this method of vaccination involved the use of a virus which had been deprived of part of its virulence, that is to say, an attenuated virus. This, however, is known now to be an incorrect view. The bacillus of black-quarter is a sporulating organism, that is, it is capable of modifying itself so as to be able to resist unfavourable circumstances while maintaining its vitality. No evidence has been adduced to show that spores can be deprived of their virulence.

During the preliminary drying of the muscular tissue any of the organisms in the vegetable or non-resistant condition either become spores or are killed, so that when drying is complete only spores remain. In the preparation of the 1st vaccine the period of heating for seven hours at 100 to 104° C. suffices to kill off a proportion of the spores. Similarly in the case of the 2nd vaccine a proportion of the spores are killed, but as the temperature is lower a greater number survive. The first vaccine is preparatory, and the second is the principal protecting agent.

Method of application of the Vaccine.

The dose for a young bovine animal is 1 centigramme of the muscle powder both of the first and second vaccines. When required for use the muscle powder is mixed with a suitable quantity of sterile water and injected under the skin. The injection must be made at some place where there is only a small amount of loose subcutaneous tissue, and the under surface of the tail about six inches from the tip is the place recommended.

After an interval of 8 to 10 days the 2nd vaccine is introduced in a similar way just above or below the spot where the first vaccine was introduced. Immunity reaches its maximum about a fortnight after the injection of the 2nd vaccine, and from that time very slowly declines. It is said that a serviceable immunity persists for about 9 months to a year.

Risks of the Method.

As I have already said, the production of active immunity always involves a risk to the animal vaccinated, and this method of vaccination is no exception to the rule.

It cannot be denied that there is a risk attaching to this method of vaccination—a risk that it may actually set up the disease in the animal vaccinated. Taking the percentage of accidents of this sort over a very large number of animals, it is found to be very low, about 1%. But unfortunately, for some undiscovered reason, these accidents are not evenly distributed. A number of animals may die at one place and none elsewhere. There is no doubt that a very valuable degree of immunity is conferred by the use of the method.

Other plans have been adopted in the preparation of vaccines against this disease, but of these I do not propose to speak.

The Administration of Bacteria deprived of part of their virulence.

There are various ways of varying the virulence of pathogenic bacteria, the variation being either in the

direction of an increase or a decrease. The processes whereby the virulence of an organism may be increased need not concern us, as such organisms would hardly be suitable as vaccine materials.

With regard to reducing the virulence, or attenuating, as it is called, a variety of plans may be adopted. Generally speaking an organism loses some, and eventually, in certain cases, all its virulence if it be submitted to an unfavourable influence of some sort. For example, the bacillus of fowl cholera may be attenuated by cultivation for long periods on artificial media without renewal. It is interesting to note that it was against fowl cholera that Pasteur made his first vaccine. He found that cultures of the bacillus kept in the laboratory gradually lost their virulence unless the growth was transplanted to fresh tubes pretty frequently. This fact suggested to him the possibility of protecting poultry against the disease by using such weakened virus. This proved to be the case. The method was never extensively used in practice, on the score of expense, but it was a successful method, and consequently of great historical interest.

In the second place the virulence of organisms may be reduced by cultivating them upon artificial media under unsuitable conditions of temperature. To this I shall return later.

Thirdly, attenuation may be produced in some instances by what is known as "passage." That is to say a series of animals other than those naturally attacked are inoculated one from the other. It often happens that in this way the virulence of the organism is increased for the animals comprising the series, but decreased for the species naturally attacked.

A vaccine of this kind was prepared by Pasteur against swine erysipelas. It was never extensively practised owing to its uncertainty, but he showed that if a series of rabbits were inoculated one from the other with the bacillus of swine erysipelas the virulence of the organism was increased for the rabbit but decreased for the pig.

A fourth plan that may be adopted to attenuate an organism is to grow it upon an unsuitable medium or a medium to which an antiseptic has been added. This plan has not been widely adopted, and need not concern us.

As an example for a vaccine prepared from an attenuated virus, I propose to describe that devised for the protection of animals against anthrax. In this instance attenuation is achieved by growing the bacillus at a temperature other than the optimum. Here, again, it was Pasteur who originated the method.

The bacillus of anthrax is one which under certain definite conditions is capable of forming spores. Not the least important of these conditions is the temperature. Pasteur found that while growth still takes place there is no sporulation above a temperature of 42 centigrade. He also found that the bacillus when grown at this temperature gradually undergoes attenuation, and finally after about a month dies, virulence disappearing entirely before growth ceases.

It is a remarkable fact that the attenuation so produced is impressed practically indelibly upon the bacillus. That is to say, supposing subcultures be made even under the most favourable circumstances, using as seed material a growth that has been incubated for a fortnight at 42.5 C., these subcultures, and all succeeding generations, preserve the same degree of attenuation as the original one. This forms the basis of Pasteur's anti-anthrax vaccination.

As in the case of the Lyons method of vaccination against black-quarter two vaccines are used. Both vaccines are broth cultures of the bacillus of anthrax. The first vaccine is a culture which is so far deprived of its virulence that in minute doses it is incapable of killing

guinea-pigs, whereas it will kill mice. It is understood that it is not necessary to make each vaccine by cultivating the bacillus in broth at 42.5 C. Once the degree of attenuation has been obtained the subcultures may be incubated at the optimum temperature without any restoration of virulence. Pasteur found that the necessary degree of attenuation was reached when the broth cultures had been incubated at 42.5 for about three weeks. Subcultures made from such primary cultures constitute the first vaccine.

The second vaccine is prepared in a precisely similar way, save that the original culture is incubated for 10-12 days only. By this time the virulence has become altered so that a minute dose will kill a guinea-pig, but will either not affect a rabbit or make it ill only without killing it.

The dose of each vaccine is $\frac{1}{4}$ cc. for an ox, and $\frac{1}{2}$ cc. for a sheep. Vaccination may be practised anywhere, the dose being introduced subcutaneously. The side of the neck, or just behind the shoulder are suitable places. Between the two doses an interval of 8-10 days must elapse.

In all cases where two vaccines are used—a first which confers but little immunity, and a second or immunising one—there must be an interval between the two administrations, because after the first dose the resistance of the animal to the particular disease is decreased, and it is in a condition of increased susceptibility. The introduction of the second dose too soon after the first might easily lead to a fatal infection. This period of decreased resistance is what is known as the negative phase of vaccination. What has been said with regard to the value of the black-quarter vaccination applies practically word for word to Pasteur's anthrax vaccine.

This method of vaccination has not been used extensively in practice in this country because in any outbreak of anthrax it is exceptional for more than one or two animals to die, and it would be in the highest degree unwise to apply the method under these circumstances, since it increases the chance of infecting the place should an animal succumb to it.

A third modification of virus that has been used as a vaccine is one that has been killed outright. This plan has not been extensively practised in veterinary medicine, although a few experiments have been made in connection with some of the suppurative diseases. I do not, therefore, propose to say anything regarding this method.

The fourth method of producing an active immunity is the introduction of bacterial products alone. This method is that applied principally in the production of anti-toxic as apart from anti-bacterial protective sera, and I shall return to it later.

There is one more method of conferring active immunity which has been practised extensively with various modifications in different parts of the world. This method is the combination of either the virulent or attenuated virus with a protective serum. Such methods are known as mixed methods. As an example of the use of the fully virulent virus associated with a protective serum may be mentioned the plan adopted in the preliminary immunisation of animals destined to supply anti-rinderpest serum. The method has been variously modified, but in the main it consists in giving a dose of fully virulent rinderpest blood and a suitable dose of protective serum.

The main disadvantage of mixed methods of protection is the difficulty of striking the right proportion between the vaccine and the serum. Should the dose of serum be too large, or the vaccine be administered too soon after the serum, the immunity set up by the serum is likely to be sufficiently strong to render the vaccine ineffectual, and consequently there will be no production

of immunity. On the other hand, if the dose be too small, there is a possibility of the vaccine setting up a fatal attack.

PASSIVE IMMUNITY.

As I have already mentioned, passive immunity is characterised by the following features. It is set up in an animal without there being any reaction on the part of the tissues of the animal receiving the serum. Secondly, it is acquired immediately, and thus in certain cases such immunity is valuable in arresting an outbreak of disease. It is of short duration. It involves no risk to the animal immunised save in one respect which I will mention briefly.

Protective sera are, broadly speaking, of two kinds, anti-bacterial and anti-toxic. In certain bacterial diseases it is not actually known how the bacteria produce their effects. In these cases no toxin can be demonstrated. One therefore calls the protective sera in these cases anti-bacterial. In other diseases, *e.g.*, tetanus, the symptoms are known to be due to a specific toxin elaborated by the bacillus of tetanus. In such a case the protective serum is termed an anti-toxic serum.

Anti-anthrax serum is an example of an anti-bacterial serum, and is prepared as follows. The first step is to confer active immunity against anthrax upon the animal that is destined to provide the serum. This may be done as already described, using the Pasteur vaccines. When active immunity is fully established the animal is given—generally by subcutaneous inoculation—gradually increasing doses of fully virulent anthrax cultures, until it can stand enormous doses. The animal is then rested for a time, generally a fortnight or three weeks, to enable it to destroy the organisms inoculated into it. The active immunity of the serum producer has now become hyper-immunity, and its serum, which immediately after the original vaccination possessed no protective or curative powers, now possesses these to a high degree. The activity of an anti-anthrax serum can never be taken for granted. It has always to be tested experimentally to ascertain its value. I will not trouble you with the technique of this testing.

When the serum is shown to be efficient a quantity of blood is drawn from the animal, generally from the jugular, with all precautions to ensure sterility. The blood is allowed to coagulate and express its serum, which is then drawn off, and after the addition of a suitable antiseptic to prevent subsequent contamination, is dispensed as required.

Value of Anti-Anthrax Serum.

A good serum should confer passive immunity on an ox in doses of 10 c.c. In this country there is not much demand for an anti-anthrax serum because the average number of deaths per outbreak is less than two. It has also very great curative powers, and provided an animal be not in the last stages and a large supply of serum be at hand a cure may often be effected.

In cases where the source of infection is persistent anti-anthrax serum is of little or no value, as it would be necessary to repeat the dose every ten days or so, and the expense would prohibit this.

Anti-toxin Sera.

The anti-toxic serum in most common use in veterinary practice is anti-tetanic serum.

Whereas no toxin can be demonstrated in broth cultures of the anthrax bacillus that have been freed from all organisms of filtration, filtered cultures of the tetanus bacillus can be shown to be highly toxic.

The method of preparing anti-tetanic serum resembles that of anti-anthrax serum save that filtered cultures of the bacillus are used instead of unfiltered ones. To commence with the dose is very small, but it is gradually increased until the serum produced will stand enormous

doses of highly virulent material. A good serum will confer passive immunity in doses of 10 c.c. The immunity rapidly declines, and after about three weeks has entirely disappeared.

Contrary to what is found in the case of anti-anthrax serum, anti-tetanic serum is of no value when once symptoms have made their appearance.

The anti-toxic power of this serum can be measured quantitatively against known quantities of toxic material.

A brief explanation of the action of anti-tetanic toxin may not be out of place. The explanation is that put forward by the celebrated German scientist Ehrlich.

In Ehrlich's view the toxin produced by the tetanus bacillus has a special affinity for certain groups of elements contained in the protein molecules of the nerve cells. By union of the toxin with these groups the physiology of the nerve cells is upset and symptoms are produced. In the animal which is to provide the serum the administration of gradually increasing doses of toxin stimulates the nerve cells, or in some way acts upon them to produce a large number of these particular groups in excess of the normal. These groups, according to Ehrlich, become separated from the parent cell and are passed into the circulation.

It is upon these groups in the protective serum that the immunising power of that serum depends. The injection of a dose of serum into an animal infected with the tetanus bacillus thus introduces into its body these groups, or receptors, as they are called. When the toxin produced by the bacilli meets these receptors union at once takes place, and thus the toxin is prevented from acting upon the nerve cells.

This view of the action of anti-toxic sera also explains why the use of anti-tetanic serum is of no avail after symptoms have appeared, for a necessary precursor of symptoms is that the toxin shall have united with the receptors of the nerve cells, and once thus united the toxin produces its effects, and the receptors in the antitoxic serum cannot again detach it.

I have said that no risk is run by an animal through the injection into it of a protective serum save one. What that one risk is I can indicate but in the briefest manner possible. This risk is the production of the condition known as anaphylaxis, or serum disease. This subject is engrossing the attention of investigators in many laboratories in Europe at the present time, and a wealth of experimental facts and details is being gradually accumulated regarding it. It may be considered quite apart from anti-toxic or anti-bacterial sera, since the condition may be set up equally well by normal and by what I may call specific sera.

Essentially anaphylaxis is the condition which is sometimes produced in an animal by a dose of serum derived from an animal of another species followed after a certain interval by a second dose of the same serum.

The symptoms of this condition are striking. In small laboratory animals the second dose of a heterologous serum may be followed by almost instant death, or there may be cramp-like convulsions followed by death within a few minutes. Accidents of this sort have been observed in Belgium and Holland where cattle have received successive doses of anti-anthrax serum derived from horses. No symptoms are produced unless a certain time, which in some experimental cases amounts only to days, has elapsed between the two doses. But once that period has elapsed accidents may occur when months pass before the second dose is given.

These effects are not produced by homologous sera, that is to say when the serum injected is derived from the same species as the animal receiving the injection.

This brings me to the end of what I have called the "Outlines of vaccine and serum therapy as applied in veterinary practice." I am only too conscious of the sketchiness of the outlines, and of the many omissions,

but, as I said at the commencement of my paper, more than this would not be possible without taxing your patience and even your endurance.

The PRESIDENT said they were all very much obliged to Mr. Sheather for his paper, and it was a matter of regret to him that he did not understand more of this important subject.

Mr. SHIPLEY said that their members were under obligation to Mr. Sheather for coming to Yarmouth and giving them such an able paper. So far as he could understand and appreciate the paper it was quite impossible that they should discuss it, but it had been a great educational treat. He begged to propose a hearty vote of thanks to Mr. Sheather for the time and trouble he had given to this paper. It would be of service to all older practitioners in the country who had not the advantage of hearing lectures in bacteriology which the younger members of the profession enjoyed. Personally he was much obliged to Mr. Sheather for the good response he made to his request for a paper.

Mr. H. P. STANDLEY seconded the vote, said he also desired to congratulate Mr. Sheather on the very excellent paper he had given, which everyone of them must regard as a treat. It was not a matter they could discuss because very few of them knew much about the subject, although it was an important one. To those who had no opportunity of attending post-graduate courses, the whole of what Mr. Sheather had explained was perfectly new, though he had probably touched only the fringe of the subject. He would like to hear a good deal more, and he hoped that Mr. Sheather would be able to come down again and go into the matter further.

The HON. SEC., supporting the vote of thanks, said he would like to associate himself with Mr. Shipley's remarks because he knew Mr. Sheather had been very busy. It was therefore exceedingly kind of him to hold to his promise. He had given them a most interesting paper which must have occupied a good deal of his leisure, when in the summer weather he would far rather have been outside.

Mr. E. WRIGHT said a good deal had been heard of this anti-toxin and anti-tetanic serum. A few years ago a man was shot not far from his stables, and was under his supervision for several days. He tried to keep people from visiting the man in order that he might be quiet, and used to see him himself morning, noon, and night. One morning he noticed he was suffering from tetanus, and immediately informed the doctor, who came at once and injected anti-tetanic serum into his buttocks. In about twenty-four hours the man could use his jaws and began to articulate. The doctor injected the serum a second time, and the man was very much better, but on the third day convulsions or blood poisoning set in and carried him off. He thought at the time great credit was due to the doctor. Had the man been kept quiet he believed that he would have been alive still. This occurred about twelve years ago.

Mr. BLOOMFIELD said that as one who seldom attended the meetings he wished to say how much he appreciated the paper. It was on a subject that was coming to the front more and more. Whenever any one like Mr. Sheather came amongst them every member would be glad to be present.

Mr. F. L. GOOCH said he understood Mr. Sheather to say the period of immunisation after the injection of anti-tetanic toxin was three weeks. He believed it was sent down from the Pasteur Institute to give six weeks immunity with a 10 c.c. dose. He thought there was a future for anti-tetanic toxin as a preventive measure. It might be preventive or curative, but he considered it was impossible to cure when the nerve cells became infected. He knew a stable that had been infected with tetanus for years. If any horse suffering from a wound was put into this stable it had always been subject to

tetanus. During the past month he had to treat an animal there, and it was the first treated successfully for four years, and at the present time was free from tetanus.

The vote of thanks was passed amid applause.

Mr. SHEATHER, in reply, said he owed the members a debt of thanks for listening to him. His object was to try to put before them a general survey of the subject. He thanked them for inviting him, and for giving him such kind attention. With regard to Mr. Smith's remarks, he did not want to make out that his paper had cost him any greater effort, but he wrote it because he understood from his friend Prof. Woodruff that the papers read before the Society were handed over for publication. Otherwise he would have spoken extempore. With regard to Mr. Gooch's statement about immunity, the various sera varied in strength dependent upon the length of treatment the immunising animal underwent while under preparation for serum. If the Pasteur Institute could prepare serum that would confer immunity for six weeks he congratulated them. As he had been in the laboratory since he qualified, he had not had much opportunity of seeing anti-tetanic serum used. He had heard it stated in practice that where there was a wound likely to be a long time healing, the dose should be repeated in a fortnight. He could only look upon cases from the laboratory point of view, which was entirely different from what they met in practice.

Mr. W. L. LITTLE proposed a vote of thanks to the President for the able manner in which he had occupied the chair. He had also given them an excellent repast and treated them in every way extremely well. They had never had a President who carried out the duties in a more satisfactory manner.

Mr. H. BUCKINGHAM seconded, and the motion was carried unanimously.

The PRESIDENT said he was obliged to Mr. Little for his very kind remarks. He felt very proud to have occupied the chair when Mr. Sheather gave them this paper, because it did them good now and again to be reminded that they did not know quite so much as they thought. He thanked them all for attending.

The meeting then ended.

SYDNEY SMITH, JUN., *Hon. Sec.*

NORTH WALES VETERINARY SOCIETY.

The annual meeting was held at "The Sportsman" Hotel, Carnarvon, on Tuesday, Sept. 12th, at 2 p.m. The following members were present; Messrs. R. S. Rowlands, President; R. Jones, Treasurer; Griffiths Evans, M.D.; L. W. Wynn Lloyd, Hon. Sec. Visitors: Messrs. J. O. Howard Rees, and W. Jones Parry.

Apologies for inability to attend were received from Messrs. J. H. Wynne, C. W. Cartwright, and Trevor Williams.

A communication was read from Mr. G. Jones Roberts tendering his resignation.

The HON. SEC. proposed that he be asked to re-consider his decision. Mr. Roberts had been a valuable member of the Society, and was an asset they could ill afford to lose.

Dr. EVANS seconded the proposition, which was carried unanimously.

THE LATE PROF. WILLIAMS.

The HON. TREASURER said this Society in common with many others, suffered a great loss by the lamented death of Prof. Williams, and he proposed a vote of condolence with the family, and that the Hon. Sec. send a letter to Mrs. Williams to express the Society's regret.

The HON. SEC. seconded. Many of us had in him a dear friend, but the whole profession and this Society in particular, lost a valuable member by the death of

Prof. Williams. Carried in silence, the members standing.

The PRESIDENT stated that he and the Hon. Sec. attended the funeral and purchased a wreath in the name of the Society. The members approved.

A letter was read from Prof. Woodruff, as Secretary of the fund which is being raised to defend the action of the L.C.C. against Mr. Kirk, asking the Society for support.

Dr. EVANS said he was not entirely in sympathy with this matter. He regarded the display of the College crest on note headings and labels as vulgar.

The HON. SEC. agreed to an extent, but pointed out that this was to be regarded as a test case, and whether we used the crest or not we should fight for the right to use it.

The HON. TREASURER proposed, and the President seconded, that a sum of three guineas be subscribed to this fund. Carried.

A letter was read from Mr. Trevor Williams suggesting that the Society purchase tooth shears for the use of members.

It was decided to defer the matter until the next meeting, the Hon. Sec., in the meantime, to ascertain the price of the instrument.

Dr. EVANS asked why subscribers to the entertainment fund of the National received no intimation of the meeting.

The HON. SEC. thought this was a real grievance which should be obviated in future. He had mentioned the matter at a meeting of the Provisional Committee, and was told by an officer of the National that the North Wales members would be written to and asked to become members of the National.

The HON. TREASURER said that only members of the National received notification of the meetings. The officers of the Association would assume that non-members would see the notices in the veterinary press.

The HON. TREASURER read the balance sheet and also the one relating to the entertainment fund. He asked what should be done with the surplus in hand, and suggested that the bulk of it go to the International Veterinary Conference fund. It was decided to consult the subscribers.

ELECTION OF OFFICERS.

The HON. SEC. proposed that in the event of Mr. Jones Roberts reconsidering and withdrawing his resignation, he be elected President. The retiring President seconded. Carried.

Vice-President.—Mr. TREVOR WILLIAMS was proposed by the Hon. Sec., seconded by the Hon. Treasurer, and carried.

Hon. Treas.—Mr. R. JONES was unanimously re-elected.

Hon. Sec.—Mr. L. W. WYNN LLOYD was unanimously re-elected.

Owing to the small attendance it was decided that the President's paper be held over.

L. W. WYNN LLOYD, Hon. Sec.

VETERINARY MEDICAL ASSOCIATION OF IRELAND.

A general meeting was held at the Gresham Hotel, Dublin, on Tuesday night, August 22nd, when the President, Prof. A. E. Mettam, occupied the chair, and the attendance included: Messrs. W. H. Wilkinson, E. A. Ryan, J. J. Vahay, John J. Small, Jas. Dodd, J. Fox, Chas. Allen, Jas. McKenny, P. D. Reavy, M. Barlow, A. C. Duncan, W. Cargill Patrick, J. Ewing Johnstone, Prof. J. Craig, E. C. Winter, John F. Healy, P. J. Howard, J. W. Peatt, R. H. Lambert, L. M. Magee, J. B. Dunlop, F. C. Mason, T. B. Mulcahy, Chris. Rea, and A. Watson, Hon. Sec.

Visitors: Profs. Jas. McCall, John R. McCall, W. Owen Williams; Messrs. H. Phelan, F. S. Ringwood, J. S. McCann, E. Proctor.

Mr. CARGILL PATRICK proposed that the minutes of the last meeting of the Association which had been printed and circulated, should be taken as read and adopted. Mr. Winter seconded the motion, which was carried.

Letters of apology for absence were received from Messrs. G. Newsom, W. Chambers, W. B. Prendergast, J. A. Jordan, Lieut.-Col. Chas. Steel, J. V. Daly, and A. J. Moffett.

The PRESIDENT said that there was one election to be proposed—that of Mr. J. B. HARE, M.R.C.V.S., Navan, who had been proposed by Mr. Magee, and seconded by Mr. McKenny. Elected unanimously.

PRESIDENT CONGRATULATED.

Mr. McKENNY said that since their last meeting a great honour had been conferred upon their President. (Applause). He had been elected President of the Royal College of Veterinary Surgeons. He therefore offered him their hearty congratulations. (Applause.)

Mr. CHAS. ALLEN seconded, and the proposition was carried.

The PRESIDENT said he desired to thank them very much indeed for their kind congratulations. He did not expect to be elected to the honourable position which he had been chosen to occupy, and when he was proposed and elected, he came to the conclusion that they were honouring the profession in Ireland at the same time they were honouring him. He told his colleagues on the Council that he thought it would be viewed in Ireland as a compliment to the profession in Ireland and he hoped they would accept his thanks on behalf of Ireland. He hoped that during his term of office the business of the College would not suffer in his hands. He hoped to do something towards steering the ship through the stormy seas and cross currents which were besetting it. At the conclusion of his term of office he trusted to hand over the prestige of the College to his successor undeteriorated. He was sure he would have the support of his professional brethren in Ireland, because hitherto while he had resided in Ireland he had never received anything but the greatest consideration, courtesy, and goodfellowship from every member of the profession. He concluded by again thanking them for the honour they had done him. (Applause).

ROARING AND WHISTLING.

By Prof. J. F. CRAIG.

Mr. President and Gentlemen.—When I volunteered to write a paper on roaring and whistling for this meeting I expressed a wish that some of the members would send me specimens of the larynx, trachea, and lungs of horses which made an abnormal respiratory sound during life. So far I have received none, but I hope you won't forget me in future when you come across such cases.

My object in bringing this paper before you and in desiring you to send specimens is to find out whether we are all in agreement as to what roaring and whistling really mean, and what is the pathology of the condition. If we are going to operate on the larynx, we must, in order that we may have a fair prospect of success, first make sure that some defect or disease of the larynx exists.

1. What is roaring or whistling?

I define roaring or whistling as a chronic condition in which an abnormal laryngeal sound is produced during forced inspiration. That definition indicates that roaring and whistling are only symptoms of a disease. If the sound is produced during expiration only, or

during expiration to the same extent as inspiration, I take it that the condition is not roaring or whistling. The difference between roaring and whistling lies in the pitch of the sound produced. In roaring the pitch of the sound is low, in whistling it is high.

2. *What are the symptoms associated with roaring and whistling?*

Attention has been drawn from time to time to the conformation, sex, and breed of horses most frequently affected with the disease. Roaring is most commonly noted in thoroughbreds and the breed of horses which are close blood relations of the thoroughbred, and it is seldom seen in cobs and ponies. It has been said that horses and geldings are more frequently affected than mares, but the evidence is not convincing. Native Arabs are seldom roarers or whistlers. Warm dry climates are also opposed to the frequent production of roaring. This condition is considered to be associated with long, fine neck, heads badly set on, and a narrow intermaxillary space. But roaring and whistling will be found in all types of horses.

Unless the horse is badly affected no abnormal sound is made during rest; it is only after a varying amount of exercise that inspiratory sounds are produced at the larynx. The amount of exercise necessary to bring out the sound depends on the condition of the horse and other circumstances. It must be carried out until the animal shows slight respiratory distress. The lighter breeds of horses must be galloped, preferably in a circle, either in the saddle or in the case of unbroken colts lounged with the long rein. Heavy horses may be lounged, or harnessed to a heavy load and driven up hill. The sounds will be heard particularly at the turning or when the horse is pulled up suddenly. The noise disappears very quickly when the animal is allowed to stand. A second trial after a horse is rested a little brings out the abnormal sounds more clearly. The cough of a roarer is often described as being deep, hollow, and prolonged.

A roarer and whistler often grunts when placed against a wall and threatened with a stick. This occurs particularly with nervous horses. The grunt is usually prolonged, and is louder if the horse's head is pulled towards the chest, and especially towards the right side. But every roarer and whistler will not grunt when feinted with a stick, and some grunTERS have no affection of the wind. It has sometimes occurred, however, that a horse which grunted afterwards became affected with roaring or whistling. Nevertheless, there is only one true test of this condition, and that consists in exercising the horse till slight respiratory distress is produced.

Fleming writes: "Direct manual examination of the larynx itself is valuable in ascertaining the condition of that organ, especially if the muscular wasting on the left side is at all considerable, and with practice the expert has generally little difficulty in pronouncing as to the existence of this wasting. When the horse's head is somewhat extended the larynx is more exposed, and the index finger can then readily feel its superior surface, which is formed by the wide expansion of the cricoid cartilage and the dilator muscles covering it. If the left muscle is wasted this surface will be found much flatter on that than on the right side." In my opinion the position of the posterior crico-arytenoid muscle is too deep to permit of a comparison between the two muscles. Again, the laryngoscope, or examination of the interior of the larynx by the hand are not practicable in the horse because of the length of the buccal cavity and soft palate.

It has been suggested that in order to be quite certain that any case of roaring is due to paralysis of the muscles of the larynx, the latter should be opened through the crico-thyroid membrane, to note the condition of the vocal chords and arytenoid cartilages. On

the side affected these organs do not move, or move only to a slight extent during respiration. This is hardly a commendable plan for the formation of a correct diagnosis. Auscultation over the larynx might be of some service in ascertaining the origin of the sound.

3. *What is the cause of the sound in roaring or whistling?*

The sound is produced by the vibration of the vocal cord, most commonly the left one. This is brought about by the inaction of the posterior crico-arytenoid muscle during inspiration. Some of the inspired air enters and fills the ventricle of the larynx, pushes the vocal cord further inwards as a projecting band in the course of the air current, which makes it to vibrate. No doubt the arytenoid cartilage will also project into the tube to a slight extent and perhaps assist in the production of the sound.

4. *What is the pathology of the condition?*

The larynx of a roarer or whistler presents certain changes in the intrinsic muscles. The intrinsic muscles of the left side with the exception of the left crico-thyroid are paralysed and atrophied, yellowish in colour, and fatty. Seldom are the muscles of the right side affected, and when they are it is usually only in company with those of the left side. The muscles involved on the left side are:

(a) *Posterior crico-arytenoid*, which swings the arytenoid cartilage outwards, carries with it the vocal cord, and so opens the glottis.

(b) *Lateral crico-arytenoid*, which swings the arytenoid cartilage inwards, carrying with it the vocal cord, and so closes the glottis.

(c) *Arytenoideus*, which approximates the arytenoid cartilages and so assists the lateral crico-arytenoid in closing the glottis.

(d) *Thyro-arytenoid*, which draws the arytenoid cartilages downwards towards the thyroid cartilage and so slackens the vocal cord. During expiration the glottis decreases in size by the action of the lateral crico-arytenoid; during inspiration it increases in size by the action of the posterior crico-arytenoid. It is noted in specimens of the larynx from roarers that the left posterior crico-arytenoid is atrophied to a much greater extent than the other muscles, and in artificial section of the inferior laryngeal nerve the same point is also observed.

5. *How is this paralysis of these intrinsic muscles of the left side brought about?*

Atrophy and degeneration of muscles may be brought about by (1) a decreased blood supply, (2) by inaction. There is no evidence of a decreased blood supply in this connection. The inaction of a muscle may be caused by some defect in the nerve supply. The nerve supply of the affected muscles is the left inferior laryngeal nerve. This nerve may be affected either at its termination, through its course, or at its origin in the medulla.

(1) Is there any evidence of a neuritis or some change of its nerve terminals?

According to Thomassen, in 99% of the cases of left sided paralysis of the larynx the changes in the recurrent laryngeal nerve are to be found in its peripheral extremities, viz., the vicinity of the larynx. The thoracic portion is quite normal.

(2) Is there any evidence that the nerve is affected through its course?

Because the left side of the larynx is affected rather than the right, an explanation has been sought in the course of the left inferior laryngeal nerve. This nerve differs from the right nerve in its longer course—it is given off opposite the fifth rib from the left vagus, and turns round behind, and gains the inner side of the posterior aorta. Here it lies between the latter and the trachea. It also comes in contact with the bronchial

and tracheal lymphatic glands. It is believed that the nerve is pressed upon or stretched by dilatation of the aorta, by pressure between the latter and the trachea, or by pressure from enlarged bronchial or tracheal glands in the course of strangles, pneumonia, pleurisy, tumours, etc. From the fact that long fine necks are often seen in roarsers, Martin supposed that during the development of the body in youth the neck becomes lengthened and the heart pushed back, straining the left recurrent nerve and pressing it at the aorta, so impairing its function. Various authorities, Ferguson in 1838, Lafosse, Trasbot, Duprey, Bouley, Colin, and Tundell have found in isolated cases enlarged thoracic glands or tumours in the neighbourhood of the nerve, or the left inferior laryngeal nerve involved in them. One would expect that if this were so Wallerian degeneration of the nerve would begin at the point of pressure and extend to the periphery, but there is no distinct evidence on this point. Fleming states that in cases of long existing chronic roaring the left recurrent nerve and its filaments have become so wasted that little is left of them except the sheath, and this even is so attenuated that a most careful dissection is required to find it. I have examined some dissection subjects in which the intrinsic muscles of the left side were affected, but did not notice any marked difference in the left inferior laryngeal nerve.

(3) Is there any evidence that the disease of the nerve is central?

In some cases no affection of the inferior laryngeal nerve in its course has been found, even after a microscopic examination, and therefore one must look for some other point at which the disease is located. It is interesting to note that the fibres of the inferior laryngeal nerve come originally from the spinal accessory nerve. It is possible that the condition is a toxic one, and that there is a central lesion which may cause some defect or derangement in the relationship between the respiratory centre and the motor centres for the laryngeal muscles.

6. *What are the predisposing causes of roaring and whistling?*

Heredity is considered to have a very considerable influence in the production of roaring and whistling. The influence may be, and probably is, of the nature of a predisposition. The progeny of roarsers do not develop the disease until they are three or four or more years old, i.e. until they are being put to strenuous exercise or hard work. Fleming gives a number of instances; Girard, Jun., cited the case of the stallion Misanthrope, two-thirds of whose produce became affected with roaring. Sometimes roaring does not appear till late in life. It has been held by some that if a horse makes a noise when he comes to about eight years old the predisposition is not transmitted. Here is a record of a case which is opposed to that opinion. A great horse-breeder of Livonia had a fine English stallion which when about ten years old became a roarer without any appreciable cause. From this time nearly all his produce were affected, but only when they reached ten years of age. Charon states that 60% of the produce of horses affected with roaring become roarsers when exposed to exciting causes. Roaring can frequently be traced through several generations of horses. The transmission of the predisposition is more certain when both parents are affected. In some cases the progeny of roarsers have never shown this defect. From Taurus a celebrated racehorse, but a roarer, none of the progeny became affected.

7. *What are the exciting causes?*

The most common exciting cause is strangles. Roaring may also follow diseases of the respiratory tract—laryngitis, bronchitis, pneumonia, pleurisy, and even influenza. How these affect the production of the disease is undecided. It may be that it is caused by some toxic action or by pressure by some exudate, e.g.

in laryngitis on the nerve terminals, or by pressure by enlarged bronchial or tracheal lymph glands, or by a consolidated lung, e.g. in pneumonia, or by thickened pleura, or by dilatation of the posterior aorta and pressure on the inferior laryngeal nerve. That is to say the exact way in which these diseases affect the inferior laryngeal nerve may not be constant, but may vary considerably. Roaring has been caused by inflammation of the jugular vein as the result of phlebotomy. Feeding with mutta pea (*Lathyrus sativus*) and lead poisoning have also given rise to paralysis of the muscles of the larynx.

Sometimes roaring and whistling appear suddenly without any apparent cause. One case of the kind was brought to my notice recently. A horse which had been known to be sound for a considerable time was examined by a well known veterinarian and a sound certificate was given. The following day the horse was taken out for exercise and roaring became manifest even at only a moderate pace. The animal remained a roarer.

8. *What is the progress and what is the effect of roaring and whistling?*

As previously mentioned, roaring may appear quite suddenly and without any apparent exciting cause, but as a rule some history precedes the appearance of the disease, e.g. an attack of strangles. The rule is that once a horse is so affected it remains for ever afterwards a roarer or whistler. A few recoveries have been noted. For example: A thoroughbred mare, Brigantine, as a two-year-old became affected with roaring, but as a three-year-old the disease disappeared, and the mare won the Oaks, Ascot Gold Cup, and Hurstbourne Cup easily. The disease may come on suddenly and remain stationary or gradually increase. Sometimes roarsers become whistlers, but the converse also occurs. Laryngitis, cold, damp weather aggravate the condition, and the distress and noise are less marked when the condition of the animal is good.

Some forms of treatment are occasionally adopted to cause temporary relief; ½ lb. of warm butter or glycerine given half an hour before exercise diminishes the noise and distress. Abstinence from water for some time before exercise has also proved beneficial, and partial occlusion of the nostril, or bulky food given to a horse have been successful in diminishing the noise, but not in increasing the working capacity. The objectionable features of the disease are the noise, the distress, and the hereditary nature. Probably the pitch of the sound is influenced by the action of the crico-thyroid muscle, which tenses the vocal cords and may influence the difference between roaring and whistling. The distress caused is far greater with roaring than whistling, and greater in some cases than in others.

The loudness of the sound is no indication as to the difficulty in breathing. Many a whistler is noted in the hunting field as one of the best known stayers. Some horses may stay although roaring like bulls. Ormonde, though an undoubted roarer, was able to distinguish himself on the racecourse. But in other cases dyspnoea appears after a time and the animal may be brought to a standstill. No doubt this has something to do with the want of aeration of the blood or the condition of the circulation.

9. *What are the diseases from which roaring and whistling have to be distinguished?*

(1) High blowing or trumpeting produced by flapping of the false nostril, quite a normal condition, need hardly be commented upon. It disappears when a horse becomes distressed or when the pace is forced.

(2) Wheezing is a condition of heavy breathing in which the sound is both expiratory and inspiratory. It is due to narrowing of the bronchial tubes from thickening of the mucous membrane.

(3) Atheroma of the nostril is a sebaceous cyst which forms on the skin of the false nostril, sometimes it

occludes its lumen and presses on the nasal chambers. A noise is then produced during inspiration. It should be observed by actual inspection.

(4) Paralysis of the muscles of the nostrils will also cause dyspnoea and an inspiratory sound, but can easily be differentiated by the appearance of the nostrils.

(5) Thickening of the mucous membrane of various portions of the respiratory tract, tumours, occasionally foreign bodies in the respiratory passages—the nasal chamber, pharynx, larynx, and trachea—fractures of the nasal, turbinated, and maxillary bones lining the nasal chambers, fractures of the laryngeal and tracheal cartilages, or injuries or malformations thereof, will all cause respiratory sounds during exertion by infringing on the lumen of the passage, but these sounds will be generally both expiratory and inspiratory. A polypus in the pharynx may cause intermittent dyspnoea.

(6) Pressure on the pharynx from empyæma of the guttural pouches, and abscesses in connection with the pharyngeal and parotid glands will cause dyspnoea and respiration sounds, but again these are both inspiratory and expiratory. Usually in those cases there is considerable swelling in the parotid region.

(7) Laryngitis, where thickening of the mucous membrane or the submucosa results from an exudate or new fibrous tissue, will also cause respiratory sounds, but the animal is obviously ill, affected with strangles or a similar disease, and the respiratory sounds are both inspiratory and expiratory.

(8) Ulcerative laryngitis, as in glanders, where it affects the vocal cords or arytenoid cartilage, may also cause roaring, because it interferes with the movements of these organs, or because it causes a thickening of the neighbouring mucous membrane. If there is a considerable thickening I should expect a distinct expiratory sound. It is hardly likely nowadays to be a common cause of confusion.

(9) Ossification of the laryngeal cartilages is seldom a cause of abnormal respiratory sounds, and I doubt whether it is a cause at all unless fusion of some of the laryngeal cartilages occur. Calcification of the thyroid cartilage in common, in fact in old horses that cartilage always contains lime salts. If fusion of the cartilages occur then abnormal sounds will be produced both during inspiration and expiration. I have heard of cases of this kind.

(10) Spasm of the glottis is a condition which has been described in the horse. It is a means of explaining those cases of intermittent roaring or whistling where an animal roars or whistles one day and not the next. It causes marked dyspnoea. It is difficult to distinguish from ordinary roaring and whistling at the time of examination of a horse for soundness, and seems to me to be a case in which confusion may occasionally result.

(11) Overlapping of the tracheal rings has also been noted as a cause of abnormal respiratory sound. It would be difficult here to distinguish it unless it affects the tracheal cartilages of the neck, which may be examined and felt.

(12) Sometimes a horse makes a respiratory sound because of circulatory disturbance, as the result of some heart affection. That can be recognised by examination of the pulse or heart after a gallop.

These then are the conditions which have to be distinguished from roaring and whistling.

I do not intend, gentlemen, to deal with the treatment of this condition. I will only say that for prevention roarers and whistlers should not be bred from, and great care should be taken of horses during the course of, and recovery from, strangles and respiratory diseases. No severe exercise should be permitted during this period, and a course of potassium iodide, arsenic tonics administered.

In the discussion I should like you to confine yourselves to answering the questions I have put to myself in the paper:

1. What is roaring or whistling?
2. What are the symptoms?
3. What is the cause of the sound?
4. What is the pathology of the condition?
5. How is this paralysis of the intrinsic muscles of the left side brought about?
6. What are the progress and effects of the condition?
7. What are the predisposing and exciting causes?
8. What are the diseases from which roaring and whistling have to be differentiated, and how would you differentiate?

(To be continued).

Charge of Cruelty to Whales.

THE LEGAL MEANING OF CAPTIVITY.

A novel case, in which proceedings were taken under the Wild animals in Captivity Act, was heard at the Penzance County Court, on Saturday, Aug. 5.

On July 1 a number of whales belonging to the species known as "pilot whale", or "ca'ing whale" (*Globicephalus melas*) were brought up by the tide and left stranded and helpless on the beach, where they were surrounded by a large crowd of people. No similar occurrence had taken place at Penzance for many years, and there appears to have been no one present with any knowledge of whales; and in some cases attempts were made to kill the animals with revolver shots; in other cases whales that were already wounded but still alive, and others that had not been shot, were slashed with knives and otherwise ill-treated. With respect to the wounding with knives, three summonses were taken out by the Royal Society for the Prevention of Cruelty to Animals, at the instance of Inspector Steele. Mr. Stuart Bevan appeared in support of the summonses, and Mr. W. T. Lawrance defended.

The case against Alfred Rogers, a billposter, was taken at length. Two police constables, Inspector Steele, and a private spectator were called to prove the facts. It was stated that Rogers had been seen with a clasp knife in his hand, the knife and hands being covered with blood, and that he had cut a whale. He had been warned by the constables, and had had an altercation with a bystander on the subject, but had afterwards taken a small clasp knife from his pocket and had made a deep cut some 4 feet in length along the skin of the whale, the animal lashing its tail, snorting, and showing by its heavy movements that it was suffering severe pain.

Dr. Chalmers Mitchell, F.R.S., Secretary of the Zoological Society, stated in evidence that whales were warm-blooded, air-breathing mammals, with brain and nervous system of a high type, that the cutting described must have caused great pain and could not be regarded as a proper way to attempt to kill the animals.

For the defence it was stated that Rogers intended by his actions to put out of their misery animals that had been wounded by revolver shots.

Mr. Bevan urged that it was immaterial whether the animals had come into captivity by the agency of man or the operation of nature, that at the time of the alleged acts of cruelty they were actually in captivity and were entitled to protection until they were released by the rising of the tide. It was contended in reply that the Act applied to wild animals, such as those in menageries, brought into captivity by man for his own purposes.

The Bench found that the defendant had unreasonably caused unnecessary suffering. They held, however, that there was no captivity within the meaning of the Act, and dismissed the cases.—*The Times*.

NOTE.—The figures for the Current Year are approximate only.

* As Diseased or Exposed to Infection

Parasitic Mange Order—V.S. Fined.

At the Birkenhead Police Court on September 16th, Warwick Fowle, veterinary surgeon, was summoned for having omitted to give notice to the police of the fact that a horse in his possession or charge was suffering from parasitic mange. He said he pleaded guilty to a technical offence, unwittingly committed.

Mr. Norman Smith, Assistant Prosecuting Solicitor to the Corporation, appeared in support of the summons.

On Saturday night, August 26th, a man named Victor Janson, a Liverpool team owner, brought a horse to Mr. Fowle's premises, and left it for treatment, stating that he had no stable to put it in. Mr. Fowle told him it was suffering from a skin disease, and he ought to report it. Janson did not fetch it away until September 1st, when he took it to Mr. Thomas Dobie, another veterinary surgeon, who found it to be suffering from parasitic mange, scrapings on different days showing parasites. Mr. Dobie reported the case.

Evidence was given by Janson, Mr. Dobie and Inspector J. R. Carnie. In cross-examination Mr. Dobie said it was sometimes extremely difficult to find the parasites, even when suspicion existed.

In defence, Mr. Fowle said he took scrapings on the Sunday morning and failed to find any parasite, but he told Janson it was a suspicious case, and that he had better report it. Janson promised to take the horse away on the Monday morning, but he never came until Friday, and meanwhile he (defendant) kept it isolated, and washed and dressed it as thoroughly as if parasites had been discovered. He made repeated examinations and found no parasite. On the Friday he told Janson to at once report the case as "suspicious," considering that the onus rested with him (Janson), as he (defendant) could not certify actual parasitic mange.

The Bench said a technical offence had been committed, and they fined defendant £1 and 9s. 6d. costs.—*Birkenhead News*.

Personal.

CRABB—On Sept. 15th, at 8 Carson Road, Dulwich, S.E., the wife of Alexander Crabb, M.R.C.V.S., of a daughter.

The Witham Committee under the Diseases of Animals Act have appointed Mr. A. J. HORNER to succeed Mr. Ainsworth Wilson as veterinary inspector for the Witham Police Division.

Mr. G. H. PICKWELL, Locum, leaves England on 23rd inst., for Singapore, to relieve Mr. C. W. Abrams, who returns to England for a few months.

Mr. AINSWORTH WILSON, who had been in practice at Witham for seven years as a veterinary surgeon, left Witham on Thursday, Aug. 31, for the Royal (Dick) Veterinary College, Edinburgh. Mr. Wilson has been chiefly known at Witham, outside his professional engagements, as a prominent advocate of the bowling pastime. He was principally instrumental in forming the Essex County Bowling Association, to which he acted as hon. sec. until March last. He was runner-up in the Single-handed Competition for the R. A. Jones' Cup in 1909, being beaten in the final by Mr. R. Jack, of the Essex County Bowling Club. He has played in two finals for the hundred-guinea challenge cup, having won both his rinks. At Witham Mr. Wilson has taken for several years a leading part in the affairs of the local bowling club. The departure of Mr. and Mrs. Ainsworth Wilson is greatly regretted at Witham, although his friends are pleased at the professional advancement he has secured.

On Wednesday evening Messrs. A. W. Garrett and J. Croxall, vice-captain and secretary, respectively, of the Bowling Club, waited upon Mr. Wilson, and on behalf of the members presented him with a case of pipes, accompanied by a letter from the President, Mr. F. P. Bawtree.—*Essex County Chronicle*.

OBITUARY.

HAROLD SESSIONS, F.R.C.V.S., F.R.G.S., Henley-on-Thames
Graduated, Lond: May, 1891.

The announcement of the death of Mr. Harold Sessions will be received with much regret in Brighton and Hove, where he was widely known and esteemed. A member of a well-known Gloucestershire family—his grandfather, Mr. Jesse Sessions, was one of the most popular Mayors Gloucester has ever had—the deceased was, as a youth, a farm student with Messrs. C. and E. Robinson, at Saddlescombe, and on their advice decided to qualify as a veterinary surgeon, a profession for which he had exceptional aptitude. He distinguished himself at the Royal Veterinary College, winning the medal for the first student of his year, and he afterwards acquired Tongdean Farm in partnership with young Mr. Rowntree, a member of the celebrated cocoa manufacturing firm of that name. At the same time Mr. Sessions practised as a "vet." and not long afterwards acquired premises in Goldsmid Road, Hove, where he became a very busy man in his profession, in which, although handicapped by a lack of physical reserve, he, by indomitable perseverance and application, attained to a considerable degree of eminence. Among other appointments he held those of veterinary lecturer at the East Sussex County Council's Agricultural College, Veterinary Inspector of the Royal Agricultural Show at Maidstone, and Veterinary Surgeon to the Southdown Hunt. Failing health compelled him to relinquish a highly lucrative practice, and travel abroad.

He served on three of the Army Remount Commissions—in Spain, the Argentine, and the United States, crossed the Andes twice, visited nearly every State in North America west of the Mississippi, and travelled through a large section of country which had previously been practically unexplored. He was the author of "Two years with Remount Commissions," a work which attracted much attention, dealing as it did with the whole question of remounts, past and future, from an agricultural, national, and military point of view. Coming back re-established in health, he became associated with one of his brothers in a big farming enterprise on the Welsh border, and, in connection with it started a business in importing Spanish donkeys for mule breeding. This involved repeated visits to Spain, and purchases he made were exported to mule breeding countries. After a time he moved this branch of his business to Henley-on-Thames. About eighteen months ago his health again broke down, and he was compelled to relinquish active business. He had since been living at Dawlish in Devonshire, and more recently paid a visit to Switzerland with the hope that the change would prove beneficial to his health. He has passed away at the comparatively early age of 45, his death being attributed to heart failure. When in Sussex Mr. Sessions followed the hounds regularly, and was a great favourite with members of the Southdown Hunt. His wife, who, with several children, survives him, is a daughter of the late Canon Gell, formerly Rector of Edburton.—*Sussex Daily News*.

Death of a Scottish Veterinary Surgeon

The oldest inhabitant of the parish of Kilbarchan died on Tuesday evening, the 12th inst. Mr. Robert Lang, veterinary surgeon, Main Street, Bridge of Weir, was born in March, 1814, and had lived under six Sovereigns. Mr. Lang was thus in his 98th year. He was born within 100 yards of where he died, his father, a blacksmith by trade, and as horseshoers the family had a wide reputation. After completing his apprenticeship Mr. Lang studied for the veterinary profession in Edinburgh, and qualified in 1838. He was the doyen of the profession in Scotland. In his later years he was afflicted with deafness, but his other faculties were little impaired. As a young man he joined the Renfrewshire Yeomanry, and was called out to take part in quelling the Greenock Riots. He was a keen Conservative, and remembered how during the election times of the Reform Bill the windows of his father's house were wrecked by a Radical mob from Kilbarchan on account of his Tory proclivities. An inveterate smoker, Mr. Lang up to his death never smoked less than four ounces of tobacco a week.—*Glasgow Herald*.

"AN UNUSUAL SKIN AFFECTION OF CATTLE." (p. 185)

Sept. 21st.

P.S.—Since writing you on the above, I have seen a typical case of the disease in a milch cow the property of a suburban owner, about half-a-mile from town, and in another district. This cow was the only animal kept, and two days ago showed swelling of both knees, and fissures at the flexures of these joints. One fore-leg is extensively swollen, and the fissures are discharging an amber-coloured glutinous fluid which forms rapidly into crusts. At the posterior aspect of the other knee an ulcer has developed. No other lesions are present, and beyond marked stiffness in progression the animal seems in good health.

E. WALLIS HOARE.

GENERALIZED PERITONITIS.

Sir,

Capt. Rainey asked a very interesting question in your last issue, viz., "Is generalised peritonitis possible as the result of 'chill'?" My experience is too slight to enable me to give a positive answer, but I remember a case which certainly seems to suggest a reply in the affirmative. It occurred many years ago. A light cart horse was turned out to grass on account of lameness. Through the field ran a small stream or beck with steep sides, say four feet deep by the same in width. At the bottom was a trickling stream of water about 8 to 10 inches deep. The horse was seen in the evening apparently well, and was found in the morning in the ditch or stream. With great difficulty he was got out and led to a loose box about a quarter of a mile away. He was covered with clay and mud as though he had struggled violently, and was much exhausted. Probably he had been some hours in the water.

I saw the case about three hours after he was released. The pulse and respirations were both increased, and there were some signs of colic, but he never lay down till he fell to die next day—about thirty hours. I remember the case well, because my diagnosis hovered between pneumonia and colic, and on looking up some notes on diseases which used to appear in early editions of Finlay Dun's *Materia Medica* I found a sentence to the effect that "the symptoms of peritonitis are a mixture of those of pneumonia and enteritis."

Post-mortem examination disclosed only slight effusion into the abdomen with some soft adhesions, and an angry red appearance of the peritoneum lining the abdomen.

—Yours truly,

W. H.

BLACKLEG

(QUARTER-EVIL. SYMPTOMATIC ANTHRAX.)

The New Zealand Official Report on Blackleg shows that the mortality from this disease has been reduced by 75 per cent. since vaccination was made compulsory. The vaccine is supplied in convenient form under the name of

"BLACKLEGIDS."

"Blacklegoids" are easily administered by means of the "Blacklegoid" Injector.

Extract from a letter which appeared in *The Veterinary Record*, January 25, 1908: "About five years ago I commenced to inoculate with Parke, Davis & Co.'s 'Blacklegoids,' and since then I have lost only one, and that was this year, out of over 900 inoculated since I commenced. I may mention that I have no interest in Parke, Davis and Co.'s preparations."

Co. Kilkenny, December 28th. 1907.

The Stock Inspector of the Pastures Protection Board, Singleton, Australia, when ordering (May 17, 1907) 200 doses of "Blacklegoids," stated: "This is the third year I have used your 'Blacklegoids,' with a result far better than I or the owners of the cattle ever anticipated. I do not know of an instance where it did not act as an immediate preventive."

Further particulars will be sent on request by

PARKE, DAVIS & Co., 50 Beak St., Regent St., London, W.

Practices for Disposal

GOOD-CLASS General Practice in first-class sporting district in the South Midlands, represented as returning between £450 and £500 p.a. is for disposal under satisfactory reasons. Further particulars in confidence will be given on application.

OLD established practice is for immediate sale, vendor having obtained an appointment. Situate in the Eastern Counties. Good agricultural district. Returns represented as being £450 p.a. C.C. inspectorship. Excellent house and stabling. Two acres of grass paddock. Price, in order to secure quick sale, £300, to include drugs, fittings, instruments, trap and cob.

AN exceptional investment for a smart man desirous of South African Practice. An opportunity of securing a partnership in an excellent equine and canine practice, established for 18 years. Represented as returning on average for last three years over £1000 p.a. Letter just to hand states: returns for first 6 months this year have been £607 10s., and that this is capable of great increase. Capital required (to include half-share of practice and valuation of surgery) under £600. References exchanged. Further information will be given to bona-fide applicants.

Wanted

PARTNERSHIP, with view to succession, in a good-class sporting practice, desired by an experienced M.R.C.V.S. with capital at command. Good horseman. Particulars will be received in strictest confidence.

THE 'RECORD' PRECISION SYRINGE.

The FINALITY of Hypodermic and Serum Syringes.

"The "Record" Precision Syringe is a piece of delicate mechanical workmanship well deserving its name. It meets **all requirements as regards aseptic conditions and accuracy and it is always ready for use.**

It consists of **metal and glass** only. The glass barrel is ground inside perfectly true to cylindric form. The Nickel vacuum piston is "ground in" into the glass barrel by precision machinery so as to fit hermetically, it slides smoothly, yet tightly, **without any lubricant.**

The cover is fixed on the cylinder with a **bayonet-fastening**; for the purpose of **thorough cleaning** it is provided with a segmental incision, by means of which it can be detached from the piston-rod by sliding it off side-ways. When **completely** taken apart the Record Syringe **forms 3 parts only: cover, piston and barrel.**

The **Needles** are provided with the original "Progressive" flat mounts. By this arrangement a good hold is afforded to the operator.

The fixing of the needle itself in the mount, by means of a smooth longitudinal guide arranged above the screw threads prevents the needle from breaking off in the mount.

EVERY SYRINGE IS GRADUATED BOTH IN C.C. AND MINIMS.

Price with 2 Steel Needles in Metal Case—20c.c. 21/- 10c.c. 17/6. 5c.c. 15/- 2c.c. 10/- 1c.c. 9/-

PRACTICES FOR DISPOSAL

WEST OF ENGLAND. Town practice held nearly 20 years by present incumbent. Receipts: 1910 £1172. Contracts produce £251. Good house containing 5 bedrooms, 3 recept. etc. garden, stabling. Working expenses light. Premium £1500.

LONDON, W. Good-class practice returning about £600 per annum, with forge the gross returns from which are stated to be about £1000 per annum. Working expenses are exceptionally low. Convenient, well-situated house, rent £70 inclusive. Forge rent £69. Contracts produce about £300 per annum and could be greatly increased by practitioner willing to accept lower fees. Premium £1000.

WEST OF ENGLAND. Practice in good breeding and hunting district, returning £600 per annum. In present hands 10 years. Convenient house with surgery, stabling etc., rent £55. Premium one years purchase.

SOUTH COAST. Country practice returning about £835 per annum, including appointments producing about £70. In present hands 24 years. The practice has been worked by an assistant who would remain if desired. Convenient house, rent £21, larger available if required. Premium £800.

IRELAND. Partner wanted to take charge of practice returning about £1200 per annum. Rent of premises £82 per annum inclusive. Contracts produce over £400 per annum. Practice has been in present hands 12 years. Premium required for half-share £500.

HEALTH RESORT. Practice returning £650 per annum, chiefly dog. Good house with large yard, stabling, kennels, etc., rent £85, or would sell freehold. Premium £750. Valuation optional.

LONDON, N. Very old-established practice returning about £1200 per annum. Good house and thoroughly convenient premises, rent £90. The practice is principally horse. Receipts are increasing. Premium one years purchase. This practice is well-known to us and can be recommended.

LONDON, S. Practice producing over £1000 per annum. In present hands nearly 40 years. Good house, with stables, kennels, etc. rent £70. The practice is principally dog with some horses and dairies. Vendor retiring. Premium one years purchase.

SURREY. Rapidly increasing, well-established practice returning about £1000 per annum. Small house with stabling, kennels, etc. Capital required, including valuation, will be about £1300. The practice is well-known to us and can be thoroughly recommended to a suitable man.

HIGH-CLASS mixed practice returning about £650 per annum. Good premises would be let on lease or sold if preferred. Premium £600.

SEASIDE. SOUTH COAST. Partner wanted in practice returning nearly £700 per annum, and capable of great increase. Incoming partner must be good allround man. Premium for half share £300.

Locum:

(Gone to India till early 1912).

73 Victoria Mansions,

South Lambeth Road, S.W.

For Disposal

SOUTH OF ENGLAND, veterinary practice (owing to ill-health). Large market town in good agricultural and hunting district. Low price, to include drugs and a few instruments. Address, 5091 V.R., 20 Fulham Road, London, S.W.

Branch Manager or Locum

PRACTICAL M.R.C.V.S. would act as above, wide experience in all kinds of practice, not afraid of work, experienced horseman, light weight, reliable, good references. Address, W. Cureton, The Chance, Upton, near Birkenhead.

For Immediate Disposal

YORKS, North Riding. Wanted, reasonable offer. Receipts over £300, good house to go with practice. Rent £12. Good agricultural and breeding district. Present owner 27 years; no opposition; C.C. appointment: introduction given. Address, 5092 V.R., 20 Fulham Road, London, S.W.

Wanted

AS assistant, unqualified man, single, for town horse practice: steady, and reliable. Apply, stating terms live in, particulars, etc. to 5094 V.R., 20 Fulham Road, London, S.W.

Situation Wanted

RESPECTABLE young man with experience of dispensing, veterinary work and book-keeping, requires position. Terms moderate, total abstainer. Address, 5095 V.R., 20 Fulham Road, London, S.W.

Assistant Wanted

FOR country practice, must be practical, reliable, a good spayer and dispenser. Apply, stating terms to Philip Turner, M.R.C.V.S., Ixworth, Suffolk.

Wanted

LOCUM, qualified, experienced town and country practice, from 2nd or 3rd October, for fortnight or more, live in. State age, references and terms, to Inglis, V.S., Alloa, Scotland.

Qualified Assistant Wanted

MARRIED, to manage a branch practice, must have good references. Address, 5096 V.R., 20 Fulham Road, London, S.W.

All communications respecting advertisements should be addressed to

H. & W. BROWN, 20 Fulham Road, London, S.W.

Tracheotomy Tubes

MISS JONES, successor to F. B. Jones, M.R.C.V.S., still continues to supply the Special Tracheotomy Tubes patented by her late father. Special terms to Veterinary Surgeons. Address, 86 Kimberley Road, Leicester.

As Manager, Assistant or Locum

QUALIFIED veterinary surgeon, experienced both town and country, wishes post as locum, manager or assistant, indoor or out. First-class references. Address, 5097 V.R., 20 Fulham Rd., London, S.W.

Locum Wanted

GENTLEMAN, competent and reliable, to take sole charge. Early part of October. References and terms at once to J., Drake House, Beighton, Sheffield.

For Disposal

OLD established country practice, unopposed by motors returns average over £300 per annum. Address, 5098 V.R., 20 Fulham Rd., London, S.W.

To Veterinary Surgeons

M.R.C.V.S. thoroughly recommends qualified assistant, who has practically managed his extensive mixed practice for last six months. Good operator, castrate standing. Disengaged shortly. Address, 5099 V.R., 20 Fulham Road, London, S.W.

Partner Wanted

IN old established horse and dog practice, on the South Coast, average returns £650. Price for half-share £300. Easy terms may be arranged. Address, 1509 V.R., 20 Fulham Road, London, S.W.

Wanted

IN a West-End London practice, a qualified assistant. State age and salary to 4509 V.R., 20 Fulham Road, London, S.W.

Assistant Wanted

IN general practice (chiefly horses and dogs). Must hold testimonials as to ability and general character. Probably a permanency to a suitable man. State age, experience and salary required to live in, to G. Parker Short, M.R.C.V.S., Torquay.

For Disposal

COUNTRY practice, genuine, doing £300 per annum and increasing steadily: C. C. appointment. Address, 3509 V.R., 20 Fulham Road, London, S.W.

To Veterinary Surgeons

M.R.C.V.S., honoursman, post graduate, qualified 1906 at present assistant in large practice, desires post as manager or junior in good-class practice. Good salary or prospects only will induce change from present post. Address, 2509 V.R., 20 Fulham Road, London, S.W.

Open for Engagement

M.R.C.V.S., well up in town and country practice, excellent credentials, open for engagement any kind. Good operator. Locum, 79 Millbrook Road, Barrington Road, Brixton, London.

Assistant Wanted

FOR horse and dog practice near London. Full particulars, etc. Live out. Address, 4099 V.R., 20 Fulham Road, London, S.W.

Wanted

INDUSTRIOUS, reliable young man to assist in branch practice, Sussex. Able to cycle. References required. Address, 1309 V.R., 20 Fulham Road, S.W.

City of Birmingham Veterinary Department

WANTED junior assistant Veterinary Inspector (Post graduate man preferred) Salary £150. Applications with testimonials to be addressed to John Malcolm Veterinary Superintendent, Holliday Street Wharf, Birmingham.

For Immediate Disposal

SCOTLAND. Death vacancy, general practice, returning £650 per ann. with shoeing forge. Price asked £100. Drugs and instruments, stock at valuation. Most suitable and a good opening for a newly qualified practitioner. Address, 4089 V.R., 20 Fulham Road, S.W.

Wanted

ASSISTANTSHIP (or locum) by M.R.C.V.S., thoroughly practical and reliable, experienced in town and country practice, good references. Address, 'Locum,' c/o Golding & Perry, Veterinary Infirmary, Eastbourne.

Vacancy for Pupil

VACANCY occurs in an extensive good-class mixed town and country practice (Midland County). This is an excellent opportunity for a young gentleman desirous of acquiring a sound knowledge of the general routine of practice. Address, 3309 V.R., 20 Fulham Road, London, S.W.

For Immediate Disposal

OLD established country practice, good agricultural and hunting district, returns average over £300 per annum. Particulars in confidence. Address, 3099 V.R., 20 Fulham Road, London, S.W.

For Disposal

SNUG practice in fashionable resort in the West, returning £200, capable of being doubled by canine practitioner. Will sell at low figure. No opposition. Address, 4087 V.R., 20 Fulham Road, London, S.W.

Locum Tenens

M.R.C.V.S., thoroughly used to country practice and holding testimonials as to ability and general character from many practitioners, is always open to engagement when not actually filling a post. Permanent Address, "Locum," 59 Gascony Avenue, London, N.W.

THE VETERINARY RECORD

A Weekly Journal for the Profession.

EDITED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1212.

SEPTEMBER 30, 1911.

VOL. XXIV.

THE REPORT OF THE I.C.V.D., UNITED PROVINCES.

The annual report of the Civil Veterinary Department of the United Provinces has just been published, and is highly satisfactory. In no part of India does the C.V.D. appear to be making better headway than in the United Provinces.

Under the same guidance as last year, viz., that of Mr. E. W. Oliver, M.R.C.V.S., as Superintendent, with Mr. C. W. Wilson, M.R.C.V.S., as second Superintendent, the activities of the Department have steadily expanded throughout the year. Much further progress has been made in gaining native confidence, with the result that outbreaks of disease are now far more frequently reported than formerly, and the old prejudice against inoculation methods is evidently beginning to disappear. Thanks to inoculation, rinderpest is abating; and the abatement was most marked towards the end of the year under report. Other diseases of course exist in plenty, and good work has been done with all, while fresh legislation has strengthened the Department's hands with regard to some.

The local hospitals and dispensaries continue to increase, both in their number and the attendances they attract. Breeding operations are extending—especially horse breeding—while the newly-created bull farm is now in working order with hopeful prospects. In fact, the only unsatisfactory feature in the report is its evidence of the old-standing difficulty of the C.V.D.—the paucity of funds and men.

The Department is still grievously undermanned, and the need for provision for the training of Deputy Superintendents is becoming more and more urgent. Nothing has yet been actually done to meet it; but communications upon the subject are passing between the Director of Land Records and Agriculture (who fully recognises the need) and the Secretary to Government. This we gather from two letters between these officials which are printed with the Report, as was the case last year. Last year, we noted with pleasure that both these letters—which might have been limited to formal submission and acknowledgement respectively of the Report—fully recognised the merit of the C.V.D.'s work. This year we see that both again do so with equal emphasis. Evidently the value of the C.V.D. is becoming impressed upon the authorities, and it should not be long, therefore, before further facilities for extending its work are accorded. In the meantime, Messrs. Oliver and Wilson have good reason for pride in their record as it stands, and may confidently await the time when they will be reinforced by a body of adequately trained Deputy Superintendents.

FATAL TETANUS BROUGHT ABOUT BY HYPODERMIC INJECTIONS OF QUININE IN THE HORSE.

By T. LISHMAN, Lieut. A.V.C., Campbellpore, India.

"The case was one of acute biliary fever, evening temperature for the first week or so reaching 106° F. on four occasions.

Three subcutaneous injections of quinine bi-hydrochloride were given on alternate days—dose 5ii. Each seat of inoculation on the following day showed a painful diffuse swelling about 9 inches in diameter (roughly).

Two or three days after inoculation, the swelling had a firm indurated periphery, and a fluctuating centre. On lancing the centre, an ounce or two of clear fluid was evacuated, leaving a cavity, the walls of which were formed by the indurated swelling.

During the ensuing days, a certain amount of sloughing took place in the subcutaneous tissue round the cavity, and tetanus (so severe as to necessitate the animal's destruction) set in about ten days after the first injection.

Section of these swellings showed an area of subcutaneous necrosis extending for fully an inch round the cavities.

It may be mentioned that most particular care was taken with regard to asepsis, and the quinine was dissolved in boiling distilled water which was allowed to cool slowly."

The writer is indebted to Capt. W. J. Dale, A.V.C., Rawal Pindi, for the above description of a case treated by him a few weeks ago. At first sight nothing very remarkable is indicated by the case, and one is apt to dismiss it by saying that no doubt, in spite of all precautions, some tetanus organisms were injected with the solution, that the syringe or needle was dirty, that the skin was imperfectly sterilised, that the wound caused by the insertion of the needle was subsequently improperly protected, or that it was what is called a case of idiopathic tetanus; and its occurrence following the quinine injections was a mere coincidence.

That there must be other ways by which the animal could have been infected is, however, beyond dispute when one is assured that the precautions taken were so complete that the above mentioned channels of infection can at once be excluded.

Quinine, as is well known, when given in large doses produces the unpleasant and dangerous condition known as cinchonism, and it was to obviate this, get a more rapid action of the drug, and at the same time prevent gastric derangement, that

hypodermic and intramuscular injections were brought into use in human practice. This method of treating malaria in man rapidly took on, and gained popularity, until it was discovered that every now and then fatal attacks of tetanus followed the treatment. In fact medical men became so alarmed that in a short time the treatment almost ceased to be continued.

The channel of infection was so obscure that a full investigation was made by Lieut.-Col. Sir D. Semple, R.A.M.C., and the following remarks are made after a perusal of his reports.

Anything which lowers vitality, such as extremes of temperature and fatigue, may be looked on as predisposing agents to tetanus. Quinine when injected into the body would also be a predisposing agent:—

(1) By paralysing phagocytes.

(2) By causing an area of necrosis at the seat of injection that would be a suitable medium for the anærobic tetanus spores to grow in.

Tetanus does not always result when tetanus germs are introduced into the body.

"Washed spores" is the term by which is known the pure spores of tetanus which have had every trace of their toxin removed by filtering and washing several times in sterile normal saline solution, and it has long been known that when these are injected into an animal they fail to produce tetanus because they are either ingested by phagocytes, or are surrounded by the tissues of the part, where they may remain for years until they find suitable conditions to grow into bacilli and produce the disease by manufacturing their toxins.

If, however, these harmless "washed spores" are accompanied into the body by anything that will cause injury to, and destruction of the tissues, and tend to prevent phagocytosis, such as earth, sand, quinine, tetanus toxin, or other bacteria, then tetanus is the result.

In short, the introduction of pure "washed spores" produces a positive chemiotaxis, and the introduction of these spores together with sand, quinine, etc., produces a negative chemiotaxis.

Regarding the fate of the "washed spores" that are injected into the animal body, without producing tetanus, Col. Semple asks the following questions at the commencement of his experiments;—

"Now the question arises, when tetanus spores are injected hypodermically, are they in all cases picked up and destroyed by the phagocytes, or are some of them stowed away locally, to remain dormant until some irritant or some other depressing influence produces favourable conditions for their liberation and growth into toxin producing bacilli?"

"Would a similar locking up of tetanus spores take place when wounds or abrasions are infected with spore-containing material?"

After referring to Vaillard and Vincent (*Annales de l'Institut Pasteur*, Jan. 25, 1891) having proved that pure "washed spores" absolutely free from all tissue-destroying agents, when injected into the tissues are attacked and ingested by the phagocytes, the investigator states:—

"It may happen even with active phagocytes that some of the spores escape destruction, and

become stowed away locally to grow and produce infection at some future time when conditions become favourable. It may also happen that some of the phagocytes require a considerable time to kill off and digest the toughest of the spores, and that phagocytes in this condition on re-entering the circulation may get stranded or lodged in a suitable site where the spores can grow and give rise to tetanus. The subcutaneous or intramuscular injection of quinine would produce such foci provided spore-laden phagocytes become lodged there."

To prove this assumption, and also to be able to answer the foregoing questions, there were carried out 19 series of the most interesting experiments, the details of which I regret would be much too lengthy to recount in this short communication.

The 1st, 2nd, 3rd, 4th, and 5th series go to prove that quinine injected one day before, the same day, or one day after "washed spores" are injected, produces conditions favourable for infection, and in addition prove that infection is more rapid where the quinine is injected before the spores.

The 6th series go to show that cold will bring about fatal tetanus in animals injected with "washed spores" and that quinine injected in addition renders the animal still more susceptible.

The following important sentence occurs at the end of the description of this series:—"One would infer from these experiments that it is possible for a latent infection to be stirred into activity by cold or other depressing influences."

The 7th series went wrong owing to the accidental contamination of the culture from which the "washed spores" were obtained.

The 8th series showed that when a culture of tetanus germs (not "washed spores") is inoculated into one part of the body, and quinine injected into another, after death the organism can be recovered from the site of the quinine injection, although it is not to be discovered in any other part of the body excepting at the point where the disease was inoculated. This certainly looks like proof of a spore having been conveyed by a phagocyte to the part that had been suitably prepared for its reception by the hypodermic injection of quinine.

The 9th series gave additional proof that the bacillus of tetanus cannot be recovered from any other part of the body when quinine and "washed spores" have been injected, excepting at the two points mentioned in series No. 8.

The 10th series proved that morphia and normal saline solution when injected do not produce conditions suitable for the growth of the tetanus bacillus.

The 11th series proved that when "washed spores" are injected with quinine tetanus is the result, but when injected with morphia the disease is not produced.

The 12th series were the same as the foregoing, only monkeys were used instead of guinea-pigs, and the same conclusions arrived at.

The 13th series proved that six months after "washed spores" had been injected into a guinea-pig, without causing tetanus, they could be recovered from the site of introduction, cultivated under anærobic conditions, and used to produce fatal tetanus in other animals.

The 14th series proved that the tetanus organism could not be discovered in the blood of animals dead of acute tetanus.

The 15th series showed that out of an examination of human fæces from ten healthy individuals in four cases tetanus bacilli were isolated. This series is concluded with the following interesting passage:—"Granted that it is possible for tetanus spores to enter the circulation from the intestinal tract where the mucous membrane is injured, ulcerated, or in any way damaged to such an extent as to be incapable of keeping back infection, what is to prevent such spores getting stranded in an injury somewhere else in the body where there is dead anærobic tissue? The hypodermic or intramuscular injection of quinine would prepare a suitable focus in a case of this kind, and so would injuries of various sorts which are constantly occurring. It seems to me that this is a reasonable possibility of infection in cases of so-called idiopathic tetanus, and in many other injuries, including quinine injections, but to say more on the subject at present would savour of conclusions arrived at in the absence of proof."

The 16th series consisted of four healthy guinea-pigs being injected on the front of the chest with three-quarters of a grain of quinine, which was repeated two days later. Two days after the second injection they were killed, and anærobic culture made from the sites of the quinine injections, when a pure growth of tetanus bacilli was isolated from one of the animals. Is this explained by the remarks on the 15th series?

The 17th series was the same as No. 16, but no bacilli were recovered. The result here goes to show the correctness of the opinion formed of the 8th series, because here no spores were injected.

The 18th series showed that 10% of guinea-pigs harbour tetanus spores in their intestinal tracts, but that all are not virulent.

The 19th series showed anti-tetanic serum to be a reliable protective against tetanus, even though quinine be injected.

Colonel Semple concludes this most interesting piece of research by advising medical men "to give a dose of anti-tetanic serum immediately before or immediately after giving quinine hypodermically."

Seeing that the horse is the animal in the world most subject to tetanus, the above abridged account of Col. Semple's most valuable work must be of more than passing interest to veterinary surgeons, who will no doubt await, with special attention, corroboration from the laboratory workers.

It has for many years been known that the tetanus organism is a frequent inhabitant of the intestine of all herbivora, but the statement that live tetanus organisms can either be imprisoned in the tissues, or conveyed about the body in phagocytes will come as a surprise to most people.

Judging from the results of the experiments, one is led to believe that an injection of quinine exercises a sort of magnetic attraction on tetanus spores that are either in the animal's body, or living in its intestines, drawing them up to the site of injection, which, owing to injury done to the tissues by

the quinine, has become an ideal anærobic culture medium where they can grow into toxin-producing bacilli and thus cause the death of the animal.

If corroboration is forthcoming, then knowledge of the disease will be greatly increased, and one will have no difficulty in understanding such cases of tetanus as that described by Captain Dale, and one will also be able to understand how cases can arise from a bruise without a sign of the skin having been broken.

Note.—If any of your readers wish to read the full account of these experiments they can be obtained from Messrs. W. Thacker and Co., 2, Creed Lane, London, E.C., or Mr. E. A. Arnold, 41 and 43, Maddox Street, Bond Street, W., in the form of a pamphlet costing about 1/- "The Relation of Tetanus to the Hypodermic or Intramuscular Injection of Quinine," by Lieut.-Col. Sir D. Semple, R.A.M.C., Kasauli, India. In India the pamphlet can be obtained from Messrs. Thacker, Spink, and Co., Calcutta.—T.L.

ABSTRACTS FROM FOREIGN JOURNALS.

MULTIPLE HÆMORRHAGES IN THE MUSCLES OF THE PIG.

Multiple hæmorrhages are distinguished according to their origin, which may, on the one hand, be toxic and infectious, and on the other hand, may be merely traumatic. In the first of these cases the hæmorrhages only form one of the manifestations of the infectious or toxic process; others, and especially degenerative lesions of the parenchymatous organs, are also observed. In cases of this nature, muscular hæmorrhages are observed coincidentally with petechiæ upon the serous and mucous membranes and even in the substance of certain organs. All these cases are excluded from an article published by Berger (*Tydschrift voor Vecartsenijkuunde*), who confines himself solely to the hæmorrhages which are seen in the muscles of pigs of which the other organs are healthy.

Ostertag, in 1890, described three cases of muscular hæmorrhages in pigs which had been slaughtered with the mallet and bled after the ordinary method. The extravasations were observed especially in the diaphragm and in the abdominal and lumbar muscles. Ostertag invariably found ruptures of the muscular fibres here, while elsewhere he found fibres containing fatty granules. He attributed the hæmorrhages to the rupture of the fibres, and thought that the cause might be found in the manner of life of the pigs. From their youth the pigs had led a very inactive life, and Ostertag's view was that the muscular fibres having become enfeebled in consequence of this, the unaccustomed movements of the pigs at the moment of slaughter and during transport may have resulted in their rupture.

This view was supported by Ostertag's further statement that these hæmorrhages are seldom seen in breeding sows and boars, which live a much more active life.

Schneider, however, has systematically examined 2,000 pigs and has found the hæmorrhages in 25.7 per cent. of them. He also asserts that these accidents are found not only in fat pigs, but also in lean ones.

Berger's own observations upon the subject have been careful and extensive. He has observed that these hæmorrhages are situated especially in the muscles which have already been mentioned, and that they have a length of from a few millimetres to two centimetres (two centimetres—about 4.5th inch) and a width of two millimetres (approximately 1.12th inch). Sometimes they are found in such abundance that the muscle has a blackish blue tint. When the affected parts are incised, a dark red liquid escapes.

Berger's observations led him to the conclusion that the condition depended upon other etiological factors than those stated by Ostertag, and this idea was soon confirmed. Berger has supervised two establishments for the slaughtering of pigs for exportation, in which the methods of slaughter employed were not the same. The methods of these establishments, and the history of each as regards the occurrence of hæmorrhages, are as follows.

In abattoir A, previous to May 1st, 1909, the pigs were slaughtered with the mallet, in batches of twenty at a time. Each pig received a blow with the mallet, but it was not till the whole twenty had been thus stunned that bleeding was practised. Moreover, the animals were not bled in accordance with the order in which they were stunned. While this method was followed the hæmorrhages under consideration were very abundant at this abattoir, two per cent. of the pigs showing them.

In abattoir B, the pigs for a long time had been killed by the American method, viz., the animal being suspended in the air by the hind limbs, and bled immediately without stunning, with the head hanging downwards. In about 140,000 pigs killed in this fashion, Berger never observed the hæmorrhages. Previous stunning was then introduced into this abattoir, and from the day of its introduction the hæmorrhages commenced to appear.

The author thinks, therefore, that the hæmorrhages may be attributed to the stunning. He has attempted to find out whether the exact method of stunning adopted exercises any influence, and he has been informed that the hæmorrhages have not been observed in abattoirs where special apparatus (the bullet, percussion, etc.) are employed. In Germany, where pigs are generally stunned by a blow from the mallet, hæmorrhages are encountered in 25% of those killed.

In abattoirs it often happens that, no order being followed, the first pigs to be stunned in a batch are the last to be bled. In abattoir A., therefore, it was arranged that no more than six pigs should be stunned at a time before bleeding, and, when this was done, it was quickly found that muscular hæmorrhages diminished.

Berger then directed that the pigs should be bled immediately after stunning; and, while previous to this he had found hæmorrhages in 2% of the animals killed, he has since, up to the present time, inspected 5,000 pigs without finding one case. Rup-

tures of the muscular fibres, however, are still observed, but as the pigs are bled immediately, the blood has little time to become extravasated into these ruptures.

It is evident, nevertheless, that hæmorrhages may be produced a certain time before slaughter by the different traumatismes to which the pigs may be exposed.—*Annales de Méd Vét.*

TRICHOSOMA PLICA IN THE BLADDER OF A DOG

Emil Balla, of Budapest, records (*Allatorvosi Lapok*) two instances of this apparently rare occurrence, *Trichosoma plica* occurs in the bladder of the fox and wolf, but has only very rarely been found in the dog (Bellingham, Neumann, von Rätz). Balla's two cases were in a hunting dog and a St. Bernard. The urine of both these dogs contained the lemon-shaped ova of this worm, which coloured yellow, probably by the urinary pigments. In both cases symptoms of cystitis could be observed.

One of these dogs died of septicæmia; but only ova, and no fully developed worms, were found in the bladder post-mortem. Probably the worms had become detached from the vesical mucous membrane after death, and had escaped at the moment the bladder was opened. The other dog was really under treatment for a skin disease; when the skin disease was cured, the animal received 1 gramme of urotropin daily for ten days, but the ova of the trichosomes did not disappear from the urine. In both cases the parasites only caused slight catarrh of the bladder.—(*Berliner Tier. Woch.*)

[It is worthy of note that Bellingham, one of the few men who have found this parasite in the canine bladder, found it in Ireland.—TRANS.]

DIPHThERIA IN SUCKING PIGS.

Wysmann describes (*Schweizer Archiv*) an infectious disease of sucking pigs which has prevailed for some decades in his district, where it is known and feared by pig breeders. One of the popular names for the affection is "thick neck." The most prominent symptoms are difficulty of breathing, hoarseness of voice, snuffing inspiration, sero-mucous or frothy nasal discharge, swelling and sensitiveness to pressure of the parotid region, anxious expression, and finally ulceration of the gums and tongue.

Post-mortem, inflammation of the larynx and the nasal passages is found; and Guillebeaux, microscopically examining the deposits appertaining to these regions, found numerous thin bacilli, in part Gram-positive and in part Gram-negative, which he regards as diphtheria bacilli. Other bacteria are also present in small numbers.

Wyssmann regards the nature of the disease as doubtful, holding that two opinions of it are admissible. It may, he thinks, be a special form of swine fever, in which the diphtheria bacilli only play the part of a secondary infection, while the primary cause of the disease is the virus of swine fever. On the other hand, of course, it may be an independent diphtheria, such as has already been repeatedly found in older pigs.—*Berl. Tier. Woch.*

W. R. C.

THE DETECTION OF TUBERCLE BACILLI IN SPUTUM. —By F. W. EURICH, M.D., Bradford.

The method of examining sputum for tubercle bacilli which is still in general use is that of preparing the films direct from the sputum by picking out of it the likely flocculi and spreading them out on a cover glass or slide.

This method has never been considered satisfactory. Many processes have therefore been tried whereby the search for the bacilli may be made easier and more sure, but none have found general favour.

A great improvement was effected by Uhlenhuth's method, which consists in making the sputum homogenous by the addition of "Antiformin," and in examining the sediment that forms on standing, or after use of the centrifuge.

Its drawbacks are that a centrifuge of high velocity is required, and that the sediment has to be specially fixed on the slide.

The necessity for such a centrifuge alone makes the original method impracticable for most practitioners. Both difficulties are overcome by an ingenious modification published by Koslow in June of last year.

As this improved method seems to be very little known, and as my results with it have fully borne out the advantages claimed for it, I make no excuse for trying to draw to it the attention of those who take an interest in sputum examination.

I have applied it now in several hundred cases, and can confidently recommend it as a great improvement upon all devices. The method is briefly thus: A quantity of the sputum is shaken up with "Antiformin" in a glass stoppered vessel, such as a measure cylinder (Antiformin=15 per cent. Liq. Sod. Hydrat.+Liq. Sod. Chlorinat. aa.) the proportion of "Antiformin" depending upon the consistence of the sputum; if the latter is very viscid or dense an equal proportion may be required; if thin, then half the amount may suffice. The mixture is occasionally shaken during five minutes, it is then diluted with a volume of distilled water approximately ten times as great as that of the "Antiformin" used, and again shaken for a few minutes. Finally there is added a mixture of equal parts of ether (methylated ether will do) and acetone equal in volume to that of the water. It is shaken once more for a few seconds, and the whole allowed to stand. In a few minutes the contents of the bottle will be found to separate into three layers. The middle layer, appearing as a more or less dense white ring, will contain nearly all the tubercle bacilli that may be present in the sputum and can be drawn off with ease by means of a pipette fitted with a teat. The density of this middle layer can be increased after it has been pipetted off, if desired with the help of a centrifuge (an ordinary hand centrifuge will answer the purpose) but it is not necessary. A film is made, dried, and fixed in the usual way by passing it through a flame.

Before staining the film I immerse it for a few seconds in 5 per cent. alkali and wash to remove the acid. If the examiner is interrupted or other-

wise pressed for time the whole mixture may be allowed to stand till the next day, or even longer, the acid-fast property of the bacilli is not affected by the delay. The sputum-antiformine mixture should be diluted with distilled, not with tap water, as the latter may contain acid-fast bacilli. The advantages of the method are—

1. Its cleanliness.
2. A special armamentarium is not required.
3. The search for tubercle bacilli is more thorough and sure.

A drawback might be found in the slight additional cost incurred by the use of ether and acetone, but the greater accuracy of the results—more than 15 per cent. of otherwise negative tests proving positive by this method—is surely adequate compensation.—B.M.J.

MR. BRITTLEBANK'S REPORT TO THE MEDICAL OFFICER OF HEALTH, MANCHESTER, 1910. (ABSTRACT.)

I beg to submit my report on the work done during the year. In carrying out the duties for which I was appointed—(1) The Inspection of the Manchester Cowsheds and Dairies as to their compliance with Manchester Regulations made under the Dairies, Cowsheds, and Milkshops Order; (2) to act as Veterinary Inspector in the working of the Milk Clauses contained in the Manchester General Powers Act, 1899.

Manchester Cowsheds.—These number 233 on 119 farmsteads, and have a housing capacity of about 2,000 cows. This number, however, as stated previously, is very variable, and is considerably affected at various times of the year by many factors such as the price of country milk, price of cattle, the effect of these causes being more evident in the case of the men in a small way of business.

Two farms have been closed during the year, and as both of them were premises so situated as to be in the midst of dwelling houses, the end of cowkeeping in such surroundings is a matter for congratulation.

In the course of the regular inspection of the city farms, 398 visits have been paid and 691 inspections of cowsheds carried out.

Nothing of any special interest has arisen during the year. The start of reasonable cleanliness has been fairly well maintained, but the irritating lapses evident in every year have still been a feature, necessitating repeated fault-finding and spurring on to do better.

Manchester Cows.—The total number of inspections made of the City cows during the year was 7,361. The number of cows housed within the City boundaries is something short of 2,000. The exact figure at the last enumeration was 1,979. The full accommodation is never utilised.

The quality of the cows kept in the City has been difficult to maintain. For some time past the price of cows has been abnormally high, and the result of this has been to tempt many to purchase cows which are not of the high quality which we require in the City, thus leading to much annoyance on the part of the cowkeepers when found fault with, as they often have been. I do not suggest for a minute that the cowkeepers of the City have purchased diseased cows. This, I know, they avoid as far as possible; but there is a class of aged cows of which there are always plenty on the market which are comparatively cheap, and which at one time were regarded as the proper class to keep in City dairies. The same impression still remains in many places. It is, for instance, common to hear in many out-lying districts certain animals referred to as suitable for town

cows. Many causes have contributed to raise the price of cows, and it would not help to attempt a discussion of these causes, but for the sake of the dairy farmer it is more satisfactory when the supply and demand are more nearly equalised, and appearances tend at present to show that the trade is returning to its more normal level.

One cow suffering from tuberculosis of the udder was found in one of the City cowsheds, and was slaughtered, the carcass being condemned. Nine other cows were removed by my orders, and seven of these were also slaughtered for me to see, and in only one case was the carcass fit for food.

The Manchester Milk Clauses.—No changes have been made in the methods of working the Milk Clauses of the Manchester General Powers Act, 1899.

Samples of milk are obtained at the Manchester and other railway stations, or elsewhere within the City, by the Food and Drugs Inspectors. These are submitted to Prof. Delépine for bacteriological examination. All samples reported by him as having been found to cause tuberculosis are followed to their source at the farm by the Medical Officer of Health (or his representative) and the veterinary surgeon.

The veterinary surgeon examines all the cows on the farm, and takes separate samples from the cows having diseased or suspicious udders. All samples are taken in sterilised bottles supplied by Prof. Delépine, and every care is exercised to exclude accidental infections. These special samples are in their turn submitted to Professor Delépine for bacteriological examination, and in this way the fact of a cow having tuberculosis of the udder is definitely ascertained. Samples from cows found by clinical examination to have diseased or suspicious udders are treated in the same way.

Extensive use is made of control samples to ensure that the inspection and examination have been satisfactorily concluded, and that all active sources of infection have been removed.

Tuberculous Milk.—During the year, 519 samples of milk have been collected by the Food and Drugs Inspectors in connection with tuberculosis. Of this number, 513 were taken at the railway stations, and the remainder from carts coming in by road. The number of farmers represented in this total is 468.

Of these 468 farmers, 274 reside in Cheshire, and 17 of them (6·20 per cent.) sent tuberculous milk; 115 live in Derbyshire, and 10 of them (8·69 per cent.) sent tuberculous milk; 54 live in Staffordshire, and 3 of them (5·55 per cent.) sent tuberculous milk; 14 live in Lancashire, and none sent tuberculous milk; 4 live in Shropshire, and none sent tuberculous milk; in addition, 6 live in Yorkshire and 1 in Leicestershire, and from neither county was any tuberculous milk received.

The percentage of farmers sending tuberculous milk was 6·41—a slight increase on the figures for 1909. It is never satisfactory to record even slight increases, but I am afraid that we have now arrived at what may be regarded as the reasonable minimum under the present powers, and the figures are likely to fluctuate from year to year no matter how vigilant the authorities may be. That a definite proportion of diseased animals must escape detection is certain, and the point to be aimed at is to keep the proportion which do baffle detection at as low a figure as possible. The local authorities in many directions are simply "beating time," they carry out the, to them, only requirement of the Dairies, Cowsheds, and Milkshops Order, namely, the whitewashing required twice a year, and so far as anything else is concerned supervision may not exist. I am bound to exclude the county of Chester from the above statement, for their progressive supervision is maintained. It is limited in its scope it is true, but is far more than is carried out by other counties affected. It may be said,

however, that the time has certainly arrived when the systematic inspection of all the cows by veterinary surgeons appointed by the respective local authorities is now urgently called for from an agriculturist's point of view as much as from a public health aspect. Much evidence has now been accumulated as to the suppression of certain animal diseases, and from an economic point of view it is to be hoped that extensive measures, not necessarily of an extravagant nature, may be enforced for the suppression of bovine tuberculosis. From the experience which I have gained from the inspection of dairy stock during the past ten years, I am certainly of opinion, as I have repeatedly stated before, that the elimination of tuberculosis from herds selected in the first instance is a perfectly sound and business-like proposition, and one which would eventually prove to be greatly to the financial advantage of all concerned. The intolerant attitude adopted by many people to this great work is much to be regretted, but is only on a par with what actually occurs in all proposals of a progressive character; and because the experiences of a limited number of people in the earlier years were not satisfactory, it does not follow that the whole of the prophylactic measures proposed to-day are unsound. I have been tempted to refer to this question, as it would seem, if one can read the signs of the times correctly, that dairy farming is entering upon a period, permanent we may hope, of well deserved prosperity, and if there is anything which would tend to ensure prosperity it is to show to the consumer that everything which is scientifically possible is being done to get for him a clean and disease-free supply of milk. I believe that the growing sense of security in the consumers has something to do with the progress of the industry up-to-date, for there can be no doubt, and I can speak from information gained first hand, that slowly but steadily the price of milk has gone up to a point making the business of milk production more remunerative. Concurrently the consumption and uses of milk have enormously increased during the last ten years, and I should imagine, in the case of a city like Manchester, out of proportion to the growth of the population. From the farmers' point of view the enhanced value of milk is gratifying, though whether the actual ratio of profit is increasing in equal proportion is not very certain, for the price of most food-stuffs, etc., has gone up. There is, however, one gratifying feature about the whole business, and that is that judging as far as one is able it would appear that dairy farming, or should I say milk producing, apart from cheese-making, appears to have a great future in this country. The amount of milk required to supply the very large and for the most part very admirable milk factories in the country is becoming an extremely important factor in the production of milk. Practically we may say that the supply of whole areas is directed to such receivers who pay good prices with reasonable security to the vendor, and the ultimate effect is that the area from which milk is derived for a place like Manchester becomes wider, with the result that many whose knowledge of the trade is limited are tempted, particularly in view of the comparatively ready payments, to embark on dairying.

As much instruction as possible is given to farmers by the distribution of circulars from this office, and at the same time farmers are asked to supply particulars as to the number of cows on their farms, etc., and we received replies to our queries from 392 farmers. From the figures supplied, it is found that on these 392 farms there were 7,474 cows, giving an average of 19 cows per farm, and if the average number of cows on the 468 farms from which the milk was examined is worked out, it will be found that bacteriological tests have approximately been applied to the milk of good cows.

In the process of actual examination and re-examina-

tion of cows on the country farms during the year I examined 2,450, and of this number 24 were proved to be suffering from tuberculosis of the udder.

It is gratifying to report that for the first time since the work began no single cow which has been proved to be suffering from disease of the udder escaped. Every cow was slaughtered in my presence, and the carcasses were inspected as to their fitness for human food, and as a result 19 were condemned as being totally unfit, and 5 were passed. This I regard as one of the most important parts of our work, and ensures the definite removal of a proportion of the diseased cows, besides being an object lesson to the individual in whose possession they have been.

One farmer was prosecuted and fined during the year for having failed to notify to the Medical Officer of Health the presence in his herd of a cow suffering from marked tuberculosis of the udder. In this case an order prohibiting the sale of milk within the City was also imposed, and before it was removed a very stringent guarantee had to be given that the general conditions would be improved. This was necessary in view of the past history. The stock on the farm was a poor one, dirty, and ill-kept. I therefore thought it desirable to advise the Medical Officer of Health that it would be necessary to apply the tuberculin test to the herd, 36 in number, and this was eventually done. The test was applied in conjunction with the farmer's own veterinary adviser, and the net result was that 89 per cent. were found to re-act. As far as was possible the re-acting cows passed out of the farmer's hands, and gradually a new stock built up. The conditions have been much improved, and the farm is kept under constant supervision.

J. W. BRITTLEBANK, M.R.C.V.S., D.V.S.M.

MR. TROTTER'S REPORT TO THE CORPORATION OF THE CITY OF GLASGOW, 1910. [ABSTRACT].

I have the honour to present for your consideration the report of the work done by this Department during the year 1910.

The number of home and foreign animals slaughtered and inspected was 422,849, of which 79,362 were cattle, 5,971 calves, 39,724 swine, 307,784 sheep, and 8 goats.

A comparison of the returns for 1910 with those for 1909 show an increase in the number of home cattle and calves slaughtered of 2,816 and 622 respectively, and a decrease in the number of home swine, sheep, and goats of 10,157, 18,707, and 3 respectively. The number of foreign cattle slaughtered shows a decrease of 7,716.

The smaller number of animals slaughtered is not due to a reduction in the amount of meat consumed, but is the natural sequence of (a) the ever-increasing quan-

ties of frozen and chilled meat placed on our markets, and (b) the lack of a uniform system and standard of meat inspection. It may be pointed out that the attention of the Local Government Board for Scotland has frequently been directed to the unsatisfactory condition under which a part of the meat supply is prepared in this country. No improvement, however, has been effected.

TUBERCULOSIS.

The most frequent disease affecting home animals is tuberculosis.

Following the precedent of former, I submit first the following statistics regarding its prevalence:

It is unfortunate that our Government authorities have not inaugurated a scheme for the gradual eradication of animal tuberculosis. In other countries more or less successful attempts have been made, but in this country, with a few notable exceptions, our stock-owners and authorities have shown a marked indifference to the matter. This is deeply to be regretted, because tuberculosis is a preventable disease, and the longer eradication methods are delayed the more difficult it will be to checkmate its ravages.

It will be noted that since 1906 there has been a steady decrease in the percentage of home cattle affected. It cannot, however, be contended that tuberculosis is becoming less prevalent, and the reason for the decrease in the percentage is that fewer cows are being slaughtered in Glasgow. The number of cows in Scotland in the month of June in each of the following years was:

1905.	1906.	1907.	1908.	1909.
437,138	434,476	438,955	431,883	435,110

It cannot be urged, therefore, that the smaller number of cows slaughtered in Glasgow is accounted for by a decrease in the cow population. The reasons for this decrease are the larger quantities of frozen and chilled meats placed on our markets, and the lack of uniformity in the system and standard of meat inspection.

ANTHRAX.

During the year six cases of anthrax were discovered.

In each case a microscopical examination was made, and the nature of the disease was placed beyond dispute by the presence of large numbers of the *bacillus anthracis*.

The precautions prescribed in the Anthrax Order were duly carried out.

NEOPLASMS.

Towards the end of 1909 I was requested by Dr Bashford of the Imperial Cancer Research Fund to forward to the laboratory under his charge all neoplasms found during 1910 in the animals slaughtered in the city abattoirs for human food. Hitherto the work of classifying these tumours had been carried out by this depart-

PERCENTAGE AFFECTED WITH TUBERCULOSIS IN HOME AND FOREIGN ANIMALS SLAUGHTERED AT ALL THE ABATTOIRS, AND RESULTS OF ADJUDICATION.

	Slaughtered.	Affected.		Destroyed totally.		Destroyed partially.		Passed.	
		Per cent.		Per cent.		Per cent.		Per cent.	
Home Cattle	67,849	8807	12.98	1297	14.73	768	8.72	6742	76.55
„ Calves	5,971	24	.40	9	.37.50	4	16.67	11	45.83
„ Swine	39,724	2432	6.12	77	3.16	7	.29	2348	96.55
„ Sheep	307,784
„ Goats	8
Foreign Cattle	11,513	186	1.61	1	0.54	11	5.91	174	93.55

ment, but, with the view of furthering their enquiries into the nature of malignant disease, this request was acceded to.

Prevalence.

During the fiscal year, 164 animals were found affected. These comprised 162 bovines and 2 ovines.

	Slaughtered.	Affected.	Percentage.
Home Cattle	67,849	162	'23
Sheep	307,784	2	'0006
Swine	39,724	—	—

It will be noted that no member of the porcine species was affected, and that these diseases were much more prevalent in bovines than in ovines. Of every 419 bovines slaughtered, and of 153,892 ovines slaughtered, 1 was found affected by some form of neoplasm. The marked difference here shown, however, does not permit of the assertion that bovines are more subject to malignant disease, the discrepancy in the prevalence being, I think, due to the greater age of many of the bovines at the time of slaughter.

Cows are kept much longer than bulls, bullocks, sheep, or pigs. Many have attained an extreme age before they are consigned to the market for slaughter, consequently they have reached a period comparable with what is known as the "cancer period" of man.

Bovines 162 aged. Ovines 2 aged.

VEAL SUPPLY.

Much of our veal supply is prepared outwith the city boundaries, and consignments of veal carcasses arrive at all hours by road, rail, and river. The age of the calves at the time of slaughter seldom exceeds seven days—the majority being two or three days old. They are, as a rule, prepared in unlicensed premises, where they are not submitted to any inspection to determine their fitness to be used as an article of human food.

During the year 534 carcasses were seized at railway stations, wharves, hide marts, etc.

It is satisfactory to record that there has been a marked improvement in the condition of carcasses arriving in the city since the present system of inspection was inaugurated, but there are still many ways by which this trade could be improved.

For instance, many carcasses are found, on inspection, to be undergoing decomposition. This is largely due to crass carelessness, either on the part of the consignor or carrier. Occasionally carcasses are consigned uneviscerated. This incomprehensible practice is probably due (a) to inability on the part of the consignor to disembowel the carcass, or (b) in order to bleach the carcass and make the flesh appear whiter. This practice of bleaching veal by the retention of the abdominal viscera in the carcass has been the cause of meat poisoning among consumers, and every effort is made to discourage it. Again, the slaughter of the calf is delayed until the vehicle which is to convey the carcass to the station is ready to start, no time being allowed for the flesh to undergo *rigor-mortis*. The result is that on arrival the flesh is soft, and the inner surface of the carcass is smeared with blood, thus presenting an unsightly appearance. Unfortunately, however, the mishandling of these veal carcasses is not confined to consignors, because during transit they are frequently subjected to the gravest abuse. They are thrown on to dirty platforms, tumbled topsy-turvy into waggons along with the usual collection of merchandise, and when they arrive at their destination they are again thrown on to dirty platforms or on to lorries.

In some instances, however, during the past few years, dealers, when consigning large numbers of carcasses, have made arrangements with the railway companies to provide them with hanging waggons. When this is done the carcasses arrive in very much better condition.

Owing to a popular outcry against the unsightly appearance of dead calves exposed to view of passengers, the railway companies some time ago issued a bye-law that no veal carcass was to be carried by passenger train unless it was covered.

Veal carcasses are consigned to this market throughout the year, but the season commences in February, and continues until May or June. On some days as many as 500 or 600 carcasses are received.

The majority are consigned to hide brokers, who distributed them among the retail trade. Inspectors are on duty at the different stations when consignments usually arrive, but owing to the hustle, imperfect lighting, and want of facilities, their inspection cannot be regarded as satisfactory. The premises of the consignees are visited at frequent intervals during the day, but as the morning consignments are delivered to the different consignees at the same time, and as carcasses are arriving at all hours of the day, it is impossible to ensure the inspection of every carcass. On the other hand, a carcass

may be inspected at the place of arrival and also on the premises of the consignee, thus entailing unnecessary labour.

A considerable number of veal carcasses are consigned to retail butchers. In some instances the consignees submit their consignments for inspection at one of the public abattoirs, but others do not, preferring to take upon themselves the onus of inspection, and plead, when any unsound meat is detected on their premises, that they had intended to submit it for inspection.

The improvements which ought to be effected include:—

(a) An age limit under which it would be illegal to slaughter calves for human food.

(b) The slaughter of all calves in a public abattoir.

(c) The prevention of surface contamination of veal during transit.

(d) The erection of examination stations to which all carcasses prepared outwith the city must be taken for inspection before being placed on the market.

(e) The inauguration of a system of meat marking to ensure that every carcass sold in the city for human food has been inspected.

INSPECTION OF FOREIGN AND COLONIAL MEAT ON BEHALF OF PORT LOCAL AUTHORITY.

All meat arriving at the Port from countries outwith the United Kingdom is inspected under the Foreign Meat Regulations issued by the Local Government Board for Scotland, in accordance with the powers contained in the Public Health (Regulations as to Food) Act, 1907.

During the early months of the year there were received several consignments of tierces from Canada, containing cow udders. An examination at the wharf showed that a proportion of the contents of the tierces opened were more or less decomposed. They were therefore removed from the wharf to premises in the city to permit of a thorough examination. The contents of every tierce were examined, with the result that, of the 66 tierces landed, only 5½ tierces were permitted to pass into consumpt, the remainder—60½ tierces—being destroyed with the consent of the consignee. The trade in cow udders has been discontinued.

During the month of September a steamer carrying meat from New Zealand and the Argentine arrived at the port. When the last portions of the cargo, consisting of quarters of beef and carcasses of mutton, carried in one of the holds, were discharged, their wrappings were observed to be more or less smeared with a black material resembling blacking. It was conjectured that there had been a leakage in some of the brine refrigerating pipes, and subsequent enquiry demonstrated the accuracy of this supposition. A cursory examination showed that the meat contained in the smeared wrappings was also discoloured. The meat formed part of parcels consigned to three traders in the city. It was impossible to thoroughly examine the affected consignments at the wharf, and they were therefore permitted to be taken to the Cold Stores under detention. A percentage of each consignment was taken for the preliminary examination, and it was found that, in addition to the discolourisation, some were bitter to taste. Portions were removed from the quarters of beef and carcasses of mutton, and submitted to Mr. Harris, the Corporation Chemist, to determine to presence of calcium chloride and arsenic. It was deemed advisable to test the latter substance, as the calcium chloride of commerce frequently contains arsenic. No trace of arsenic was detected, either in the first series of samples submitted or at any subsequent date. The presence of calcium chloride was, on the other hand, determined in a considerable number of samples. The quantity varied in amount—the largest found being 1.96 per cent.

SUPERVISION OF MILK SUPPLY.

The supervision of our milk supply cannot be regarded as satisfactory. The Corporation of Glasgow possess in Sections 24 to 27 of the Glasgow Police (Amendment) Act, 1890, unique powers so far as this country is concerned, but even these cannot ensure a pure supply of milk from healthy cows.

Following the issue of the Report of the Royal Commission on Tuberculosis in 1898, the Local Government Boards of England and Scotland in 1899 amended the Dairies, Cowsheds, and Milkshops Order, extending the word "disease," which had hitherto only applied to those diseases scheduled under the Diseases of Animals Acts, to cover tuberculosis of the udder of cows. Undoubtedly this was a move in the right direction, but, unfortunately, it is optional on the part of Local Authorities to adopt the Dairies, Cowsheds, and Milkshops Order, and thus this amended Order has been, to a large extent, inoperative. This inaptitude on the part of Local Authorities may have been due to the inadequacy of the powers granted, because they were only empowered, in the event of their veterinary surgeon detecting a case of tubercular mastitis, in order that the milk of the diseased cow

(a) shall not be mixed with other milk;

(b) shall not be sold or used for human food; and

(c) shall not be sold or used for food of swine or other animals, unless and until it has been boiled.

It must be admitted that it is impossible to ensure that the owner of the cow will carry out these instructions. The issue of such an Order can only be described as a half-hearted measure. It is simply tinkering with a vital question affecting the health of the whole nation. A pure and wholesome supply of milk is a national necessity, and in all future legislation the Imperial Authorities ought to see to it that every Local Authority discharges its duty in this all-important matter. No Local Authority ought to be in a position of either quietly ignoring or carrying out this all-important work in a half-hearted fashion. The recent report of the Royal Commission on Tuberculosis has emphasised in no uncertain manner the importance of this question, and every endeavour ought to be made to detect at the earliest possible moment every cow affected with an open form of tuberculosis.

INSPECTION OF MILCH COWS (CITY).

The cowsheds in the city were visited on 528 occasions, and the milch cows housed therein were examined, with the result that 69 were found affected.

INSPECTION OF MILCH COWS (COUNTRY).

Farms situated outside the city were visited on 540 occasions, and 15,363 milch cows were examined. 157 were found affected.

LANCASHIRE VETERINARY MEDICAL ASSOCIATION.

The quarterly meeting was held at the Grand Hotel, Manchester, on Sept. 7th, the President, J. W. Brittlebank, Esq., Manchester, in the chair. The attendance included Messrs. Ferguson, Whitehead, A. Munro, jun., Carter, Stent, Ellis, Dobie, Wolstenholme, Woods, Mattinson, Taylor, Locke, Price, Michaelis, Wilson, and Ackroyd.

Apologies for absence were received from Messrs. Faulkner, Packman, McKinna, and Darwell.

The minutes of the last quarterly meeting were taken as read on the motion of Mr. Stent, seconded by Mr. Carter.

The PRESIDENT reported having attended, along with Mr. Locke, the dinner of the Liverpool V.M.A. They were received with the utmost hospitality and had the pleasure of listening to an interesting address on agricultural education by Mr. John, M.P. The whole function was a great success, as was only to be expected when they considered who had the management of it.

Mr. CHARLES SECKER SMITH, Barnsley, and Mr. JOHN HOLROYD, Blackburn, were unanimously elected as members of the Association.

Correspondence.—A letter of resignation under date of 18th July, inst., from Mr. E. S. Gubbin, Hyde, was read. The resignation was due to removal from the district and was accepted with regret.

A letter of resignation was received from Mr. W. S. Worthington, Wigan. This was due to ill-health, and it was resolved that a letter be sent to Mr. Worthington regretting the cause of the proposed resignation and asking him to reconsider the matter.

A letter dated August 16th from the Editor of *The Veterinary News* was submitted in reference to the fund which that paper is organising for the purpose of assisting Mr. William Kirk in the appeal raised by the London County Council to compel veterinary surgeons to pay for the use of the College crest.

Mr. LOCKE proposed that the matter be referred to the Council.

Mr. CARTER expressed the opinion that they ought to subscribe to the fund. Personally he intended to do so, and he hoped every member would. He agreed with the proposal to refer the matter to the Council with a recommendation that a sum of two guineas be forwarded towards the fund.

Mr. TAYLOR asked what the state of the litigation was. The Secretary replied that Mr. Kirk had already won the case, but the London County Council were appealing and threatened to take the case to the highest Court if necessary.

The SECRETARY reported that their invitation to the National Veterinary Association to hold their next annual meeting in Lancashire had been accepted.

The PRESIDENT moved that the matter be referred to the Council to make such arrangements as may be necessary.

A letter from Mr. Gofton, Hon. Sec. of the Committee of the National Veterinary Association was read. This conveyed the resolutions passed at Carnarvon on July 25, respecting the arrangements to bring the amended rules into operation at the annual meeting of the Association to be held in 1912, and also ensuring that existing members of the National Association shall become members under the amended rules.

The PRESIDENT pointed out that the Lancashire V.M.A. had already expressed their intention to associate themselves with the scheme, and there was no necessity to pass any formal resolution.

Other business.—Mr. CARTER asked what was being done towards subscribing to the International Congress to be held in 1914. Other societies were already contributing.

Mr. LOCKE replied that the matter had already been informally brought before the Council by Mr. Lawson, and it was decided to leave it for consideration at a later date.

Mr. WOLSTENHOLME rose to announce the death on Sept. 5th of Mr. H. D. Chorlton, a former Secretary of their Association, and a member for many years. A vote of condolence with the widow and family was passed in silence.

The PRESIDENT then reported the sad news of the death of Prof. Owen Williams on Sept. 6th. The Professor, he said, was a gentleman known intimately to many of them and held a honoured position in the profession. Personally, as an old student of the New Veterinary College, he felt the loss very deeply. He

would remind the members that Prof. Williams was an honorary member of the Lancashire V.M.A. and the Society had suffered a grievous loss. His sympathies went out to the widow, and he thought they could do no less than pass a vote of condolence with her in her trouble.

Mr. TAYLOR said that having known Prof. Williams so many years he desired to associate himself with the expressions of sympathy, and trusted that a letter of condolence would emanate from the Society to Mrs. Williams. Prof. Williams had done a great deal for the profession, and he (Mr. Taylor) was sorry that the Professor had not lived longer to keep his father's name in actual remembrance amongst them.

Mr. CARTER also wished to associate himself with these remarks. He had known Prof. Williams in boyhood, and had been associated with him ever since.

A vote of condolence was passed in silence, all present standing.

The PRESIDENT here desired to say how glad he was to see Mr. Taylor amongst them again after his serious illness.

PATHOLOGICAL SPECIMENS AND CLINICAL CASES.

Mr. NOEL PILLERS: I have here a few slides, and although harping on the old subject of parasites, I think there is a little clinical interest attached to them. The first three slides are of the dog flea. There is an old specimen which shows the usual character of the dog flea which is distinguished by its combs. The second slide shows the eggs, and the third is the larval stage. A veterinary surgeon was consulted concerning a little Pomeranian dog from which, whenever it shook itself, a number of pearl white bodies dropped. These bodies measured about .8 mm. He also found on the dog two or three small things which looked very much like maggots, about 4 mm. long. He wished to know what they were. The pearl white bodies are the eggs of the dog flea and the maggots are the larvae. It has been shown that in long-haired dogs it is possible for the whole life history of the flea to take place on the host. The adult lays the eggs, and according to the temperature these eggs hatch out in from six to twelve days, and after another five or six days, bringing the time up to about seventeen days, these larvae turn into a nymph in a cocoon and this soon turns into an adult.

The fourth specimen is a small nematode from the caecum and colon of the horse, viz., *Probstmayria vivipara* sometimes called *Oxyuris vivipara*. It is two to three m.m. long, and is so small as to escape observation unless looked for microscopically. It is of interest as it is probable that it is sometimes mistaken for immature forms of some of the larger nematodes of the horse's bowel.

Mr. WHITEHEAD submitted a specimen of tuberculosis of the intestine of an old cow. He brought it forward as being from the most marked case of ulceration of the bowel he had ever seen.

Mr. WOLSTENHOLME gave the history of a mare which died from dilated and hypertrophied heart. On first receiving the animal in hospital on January 22nd she was practically pulseless—it was not possible to feel more than a tremor. Her temperature was 101.8, pulse 72, and very weak respiration, and this went on from the end of January to 30th May, when she had colic and died. Post-mortem examination revealed simply this dilatation and hypertrophied condition. The mare was in the prime of life: the heart weighed 20lb. The only symptoms were this pulselessness, raised temperature 100 to 106, and somewhat increased respiration. She ate and lay well, her appetite was good, and the bowels were normal all the time.

Mr. STENT reported cases of poisoning in pigs from eating green potatoes. The owner had picked up some green potatoes lying on the land and given them to his

pigs (three weeks old). Half-an-hour after feeding they began to be ill, and two died. There was no eruption on the skin, and a post-mortem revealed nothing. He had seen a similar occurrence in a pony, which did not end fatally, although the animal had been very ill.

He desired to hear an opinion as to the efficacy of nuclein in the treatment of pneumonia. He had used it hypodermically on three horses out of seven under his treatment, and these were longer in recovering than those not so treated. In treating dogs with it he had formed a very favourable opinion of its use. He had recently treated a Great Dane suffering from bad distemper; he gave an injection of 4 c.c. of nuclein and the following day the hemorrhage ceased; two days later the appetite returned and the animal did splendidly.

Mr. TAYLOR had found nuclein of marked assistance in cases of pneumonia in horses. He found that the best time to employ it was at or during the crisis.

Mr. MATTINSON had also used it with success. He reported a case where he had been engaged to castrate a horse. The owner asked him to take the colt away, but on arrival Mr. Mattinson found it to be not in a condition for castration so turned it into his own field, and told the owner, who requested that the colt should remain there until ready. About a month later he was surprised to receive a message that the colt was lying dead in the field. A post-mortem examination revealed the cause of death to be due to yew poisoning. The yew trees were situated over the fence on another person's estate, and the question of liability arose. Legal opinion was taken, and was to the effect that the owner had no claim for the loss inasmuch as the colt had been placed in the field by favour and not for reward.

He also reported a singular case very suspicious of foot-and-mouth disease. This was a cow, recently calved. The cow could not bear the mouth or tongue to be touched, and could not eat. Treatment was ineffectual, and examination after death revealed only this sore mouth.

Mr. TAYLOR submitted a question recently put to him—Is a horse that will not lie down an unsound animal? A person bought a harness horse warranted sound and a good driver. There was no fault to find with either of these conditions, but the animal refused to lie down. Mr. Taylor caused amusement by stating that the reply he gave was that it might constitute unsoundness or it might not, but he could not tell without examining the animal as to any abnormal condition or disease. Mere refusal to lie down in the absence of any symptom of abnormality did not appear to amount to unsoundness. The solution was that in a few days the horse did lie down.

Mr. CARTER asked what the stable was paved with. He had known fresh horses brought on concrete that had been months before they would lie down.

Mr. WOODS stated that he had bought a pony that would not lie down in the stable, although it would do so in the field. The animal was perfectly sound in every way.

The PRESIDENT reported a case occurring in the course of his work which showed how difficult it was sometimes to diagnose tuberculosis of the udder, a difficulty which is now becoming very common in his district, as owing to the supervision exercised the farmers generally will not keep a cow which is in any way suspicious. In this particular case, occurring on a farm in Cheshire, the sample of milk taken showed that tuberculosis had been produced in the inoculated animal. On visiting the farm 46 cows were examined, but he could find nothing to direct his suspicions to any particular cow. Careful enquiries as to the disposal of any cows prior to his visit elicited nothing, and finally he came to the conclusion that the information was unreliable, and that a cow or cows had been sold. However, a mixed control from

the whole herd was obtained, and on being submitted to the inoculation test was again found to cause tuberculosis. He again visited the farm, but was still unsuccessful in discovering any suspicious cow. The herd was then divided into groups, and five samples representing each the milk of eight cows, and one the milk of six, were taken. Subsequently the milk of one group was found to cause tuberculosis, and on visiting the farm again one cow (in good condition) showing only the slightest possible symptoms of udder disease was found. The whole lesion discoverable by manipulation would not have covered a sixpence. The remarkable feature about the case was the length of time (three months) which elapsed before even suspicious lesions were discoverable.

Referring to the inadvisability of expressing decided opinions, he had a case quite recently where he diagnosed tuberculosis of the udder in a heifer—a comparatively rare occurrence, it is true. The lesions were certainly very slight, and the heifer appeared in good health, although examination of the chest gave decided signs. The farmer was somewhat upset, and called in a certain practitioner in Cheshire to examine the heifer, which he did, and subsequently stated that it was ridiculous to condemn the beast, as he was as sound as a bell; and he made some very uncomplimentary remarks regarding the clinical skill of many veterinary surgeons and of the speaker in particular. However, the gentleman (?) was invited to attend the post-mortem, but failed to do so and sent no excuse. Incidentally it was found that the diagnosis was amply confirmed, and the carcase was condemned as unfit for food.

He did not for a minute complain about differences of opinion, it was only natural that people should differ, but he did think that it was a gratuitous piece of impertinence for one man to pass reflections upon the ability of another veterinary surgeon, even although the latter were the occupant of a public position.

Mr. WOLSTENHOLME instanced a case of a horse having been sent to the forge. As they were busy a veterinary surgeon suggested that the horse should not be allowed to stand in the street, but offered the use of a loose-box. The offer was accepted. The box was a good size and well paved, but when the horse was brought out it was found to have got a pastern split in three places. The owner of the horse wanted compensation from the owner of the box.

The meeting was closed by a vote of thanks to those members who had brought up cases for discussion, proposed by Mr. Price, seconded by Mr. Locke.

G. H. LOCKE, Hon. Sec.

VETERINARY MEDICAL ASSOCIATION OF IRELAND.

(Continued from p. 170.)

ROARING AND WHISTLING.—DISCUSSION.

Prof. CRAIG was loudly applauded on concluding the reading of the paper.

The PRESIDENT remarked that they had had a very interesting, not to say elaborate paper, from Prof. Craig, which offered plenty of food for reflection. He had put plenty of material before them to ensure a good discussion. There were present a good number of practitioners whose opinions were worth having, and he was sure they would have reason to rejoice that Prof. Craig had brought forward the paper, because he had little doubt that many present were anxious to give their opinion upon this debatable subject.

Mr. McKENNY said that immediately after hearing so able a paper as that read by Prof. Craig on so interesting and important a subject that it required due considera-

tion previous to seriously discussing the various questions that had been raised, especially as there was great diversity of opinion or many of the questions, and general definite conclusions had not been established relative to them. He therefore proposed that the discussion should be at least extended until the next meeting of the Association. However, on the present occasion he noticed that Prof. Craig in his remarks relative to the causes of whistling and roaring, omitted to mention the affections arising from gastric troubles, such as indigestion, etc. The Professor told us that on this occasion he wished to confirm his remarks to "whistling and roaring" resulting from paralysis of the recurrent laryngeal nerve, but in doing so had omitted to mention the origin of the nerve—pneumo-gastric—and if he had done so it was a serious omission. Mr. McKenny was not certain that it had been omitted, but he was fairly certain that in the enumerating of the diseases affecting the nerve he had only mentioned those of the respiratory organs, and had not cited the gastric derangements. Thus if the subject is to be considered in its entirety, if the causes of paralytic whistling be only considered as arising from diseases affecting the respiratory organs, most erroneous conclusions would be arrived at, as paralysis of the recurrent laryngeal nerve is due to affections ensuing from derangements of the pneumo-gastric nerve. Therefore as this nerve is common to the lungs and stomach, ailments affecting these organs must be considered to arrive at correct conclusions on the subject. Without this knowledge there are many important facts which we could not explain, but with it we can readily understand such matters as why whistling arising from chronic disease of the lungs more seriously affects a horse's power of endurance than if the abnormal sounds were due to gastric affections. Granting either organ has become chronically affected, whether whistling has taken place or not, the effect on a horse as to its capability to perform its requirements are vastly different in each case, that is, allowing that the horse otherwise is in good condition.

The PRESIDENT reminded them of the questions Prof. Craig had asked—What is roaring? What are the symptoms? What is the cause of the sound? What are the predisposing and exciting causes? and For what diseases may it be taken?

The PRESIDENT then introduced two gentlemen who arrived at the meeting, Dr. McCall, of the Board of Agriculture, and his brother, Prof. McCall, of Glasgow, who were heartily welcomed.

Mr. CARGILL PATRICK remarked that they had listened to a very interesting paper. Prof. Craig had put a very difficult problem before them to solve. He thought the causes were so numerous and varied that they were quite in the dark as to the causes of roaring and whistling, as they got it in so many different forms. They sometimes had it due to the condition of the stomach. He had known cases where you could bring out a horse and hear him across the street whistling, and after half-an-hour he might be sound. For that reason he did not think for a moment that he would attempt to solve the question at all. He did not agree with Prof. Craig's definition of roaring. He said they only got it during certain stages of respiration. He considered roaring was an abnormal sound—in either inspiration or expiration. In other cases they had grunting taking place, which was supposed to be sometimes due to consolidation of the lungs. A great many cases of roaring were due to some nerve degeneration. They could have an abnormal sound due to the thickening of the mucous membrane. So many different points had been brought forward that he thought they would want to read the paper, and take up the points and discuss them. It was due to Prof. Craig to do that in order to give his paper justice; the points could be discussed

as fully as they should be. He suggested that it be brought forward at the next meeting for discussion.

Mr. P. D. REAVY seconded Mr. Patrick's suggestion.

Mr. MASON said he was sorry he was not present to hear the whole of the paper, but he was interested in Mr. McKenny's remarks, although it was difficult to follow him through his meanderings on the pneumo-gastric nerves. He was not sure if Prof. O'Connor was present, but if he was, he would like to hear his experience of the new operation.

Mr. WINTER said it was hardly fair after a hard day at the show to be expected to answer these questions. There was no question as to the excellence of the paper. He agreed to the suggestion that they should get a little more time before they answered the questions. There was one point they might touch on at the next meeting, and that was a point which had a legal aspect. It was as to exact time that roaring or whistling may begin. There was another question that puzzled him, and that was if it was due to changes in the nerve tissue and the paralysis of cartilage connected with the vocal cords, why would a horse whistle at first and subsequently go sound. He knew a case where Mr. Patrick rightly rejected a horse for a whistler and he immediately afterwards galloped perfectly sound. He had seen horses rejected at shows, which galloped sound immediately afterwards on appeal. Both opinions were perfectly right, and yet the horse was wrong. He had had some bitter experiences of whistling. He had a good horse and rode him in the morning. A customer came along and bid him a good price, which he refused. He rode the horse again in the evening and he was wrong, and wrong ever afterwards. It is a question—Was that horse a whistler from nerve disorder or concentration of the mucus in the throat. Does a whistler ever recover? It was a well-known fact that whistlers and roarers did recover. In that case what was the whistling due to? He thought it was due to some tumefaction of the larynx pressing on the nerves. Then, again, whistling became incurable. It was a point they could never come to agreement upon, because they could not examine the organs involved. He did not know if conformation had anything to do with it, but there was no doubt that heredity had had a great deal to do with it. Whether the tendency was hereditary or the disease he did not know. There was a celebrated sire in a stud they all knew and most of his progeny turned whistlers and bad roarers. He understood the new operation was tabooed—rather unfortunately, because they might get information from men who had tried it. In opening the larynx they saw different conditions. In a horse which was a bad whistler or roarer they sometimes saw little change. He hoped a discussion on the paper would be arranged on a future date, so that they might not be tied down to the questions that Prof. Craig had asked.

Mr. HOWARD was of opinion that the Association was to be congratulated on having such a paper before it. It was a troublesome disease. Prof. Craig had given them a definition of roaring, but he did not think it was the definition accepted by the everyday workman. Unfortunately the profession did not hold an opinion of its own; it was very considerably mixed up with the opinion held by the general public and horse-owners. The accepted definition of whistling was that it was an abnormal sound produced during expiration or inspiration by the animal if put to severe exercise. It was for the veterinary surgeon to say what that sound was. The ordinary public they had to deal with had that as their notion of roaring, and it was one of the aspects of roaring that he would like to be discussed and to be cleared up, because he thought it would do good to members of the profession who had to examine horses as well as to the public who had to buy them. One of the greatest benefits accruing at any time to the profession followed

when they were the means of educating the public to understand better what they had to do. He thought the public generally recognised when they gained any benefit from the profession. It was a common practice of veterinary surgeons when examining a horse, and it was expected by the public that if that horse made a noise of whistling or roaring it had to be cast. That was perhaps, the most unfortunate aspect of the whole matter, because they all knew of horses which sometimes made a noise, and afterwards when put to severe exercise, would be found to be more or less right. They all knew it was a common thing to get a horse to go and have a ride, and he jogged away out of the yard and they thought he made a noise. Then they got into the field and did three miles over the country, and never heard anything. He always thought such a horse was sound, but it was not fair to the client sometimes. If he passed such a horse as that sound, as he believed him to be, someone else came along, and because he heard that little noise cast him. So the client suffered. Prof. Craig had answered very extensively the questions he put himself. He had classed strangles as a disease of the respiratory organs, and one which was often-times followed by roaring. He (the speaker) did not regard strangles as a bad disease. With regard to heredity of roaring, he thought the consensus of opinion seemed to be that heredity was indeed very well proved with regard to the transmission of roaring. He thought there were several cases on record that horses had made good recoveries from roaring and whistling, and after considerable time of being roarers and whistlers. He did not say it was very usual, but it was common enough with horses that became roarers after such affections as strangles. Horses from good stock had a chance of becoming sound and well again. What part did Prof. Craig think was played by hot climates on the state of the larynx? Some well-known roarers had left Ireland and England, and when they got to places like South Africa, South America, and Australia they became sound. (Applause).

Mr. MAGEE said that Prof. Craig had asked several questions, but that many need not be answered, as he had answered them himself. For instance, he asked "What are the predisposing and exciting causes?" He thought Prof. Craig had mentioned every one of them. With regard to the first question—What is roaring?—he was inclined to agree with Mr. Patrick and Mr. Howard that it should not be looked on as an abnormal sound alone, because he was inclined to be of that belief until about a year ago when he met his first roarer, which made its first sound in expiration. He had to gallop him before he was satisfied that he was roaring. He was not a usual case of roaring, but he was roaring during expiration.

Although the subject of the new operation was not to be discussed, there were a few things in connection with it that had a bearing on the paper, and one was in connection with the horse he was speaking of. He operated on the horse, although he had not much hope of recovery, but it eventually made a complete recovery. After three months he made an abnormal sound, but a month later he was perfectly sound. In that case the left arytenoid cartilage and the vocal cord was only slightly affected. They were not badly paralysed. Another thing the new operation had revealed was that it did not follow that because they found on looking in the larynx of the vocal cord or the arytenoid cartilages that the trouble was not there. He had done a number of these operations and found that Prof. Woodridge was wrong. He knew a horse which roared owing to strangles. He was asked his opinion as to the advisability of operating on him. He thought at the time that a horse that became a roarer owing to strangles was not likely to yield to operation. He thought it was worth trying, however, and operated about three months

ago. He examined him last Thursday, and he would now put him before any veterinary surgeon to be galloped for his wind. He had hard luck over the horse, because he nearly went before Mr. Allen. He was called in by the judges for a prize, but did not get one as he was thick about the neck. He would be able to tell Mr. Allen that he had passed a horse which was a roarer.

Mr. ALLEN: I bet you 5/- to £20 he is not sound.

Mr. MAGEE: I bet you if I put him among five other horses you will not pick him out.

Mr. ALLEN: Done.

Mr. MAGEE said he wondered why Mr. Allen examined all the throats, especially as he did at the Navan horse show. He would bet Mr. Allen on another point—that he would not show him the wound he made in the horse's throat.

Mr. ALLEN: I bet you a sovereign I will.

Mr. MAGEE: Only if you shave the neck.

Mr. Magee, continuing, remarked that the horse had been crabbed by people who had not seen the operation and it was not fair. He supposed the symptoms of roaring were hearing an abnormal sound of roaring and whistling, and also grunting as a rule.

The subject of the grunting was an interesting one, too, and was a subject on which there would always be a difference of opinion. When he was in the London Veterinary College Prof. Macqueen, an eminent veterinary surgeon, said that grunting had nothing to do with whistling or roaring or roaring. At the time he believed that, but as he got experience he had changed his opinion. He was conscious of the fact that although he might be casting horses which were grunters as not being sound in wind, the horse might remain sound all his life. Therefore grunting was not a sign of whistling and roaring, or that the horse would become a roarer or whistler. What is grunting? That was a question he had never heard asked at a meeting, nor answered. The conclusion he had come to was that grunting was, as a rule, due to the inability of the horse to close the glottis on the arytenoid cartilage. If a horse had perfect use of the epiglottis he would hermetically seal the larynx. He thought grunting was the vibration of the epiglottis with the arytenoids.

With regard to strangles he had never seen a case of it affecting the respiratory system. He knew it did often lead to pneumonia and pleurisy. He considered that they should postpone the discussion to a further meeting, and thanked Prof. Craig for his paper. (Applause).

Mr. HEALY said he had the experience of buying a horse for £18. He was a roarer and was cast by a veterinary surgeon. He (Mr. Healy) hunted the horse for two seasons, and then it took cold. Blisters on the throat followed, and he was put to grass. The following season he became a sound horse and he was sold for £100, having been passed sound. He would like to know the cause of roaring in that case. Practically there was no test to find out what was the cause of roaring.

Mr. J. B. DUNLOP said he thought in bad cases or aggravated cases, roaring occurred during inspiration and expiration. There was no doubt that the predisposition to the disease was hereditary. He had a considerable amount of sympathy with what had been said about grunting. It was a premonitory symptom of roaring. There might be a certain paralysis of the muscle which expanded the arytenoid cartilage and the larynx was caused to contract, and then a sound was emitted. He had known cases of roaring to recover—several cases.

Prof. M'CALL, after expressing regret that he did not hear the paper read, said he had listened to some of the remarks and there were one or two points he would like to touch upon. He thought they, as a profession, should devote some time to the discussion of roaring. The more he saw of the disease in its various phases the more he was inclined to the opinion that there were

different opinion which had been confounded by many. They were led to believe it was owing to abnormal conditions of the recurrent alteration of the larynx. There were so many conditions which might give rise to roaring which was distinct from what was ordinarily recognised as roaring. The time was opportune for such meetings as they had that night. A speaker had asked if grunting was a symptom of roaring. He did not know what the feeling of the meeting was, but he thought they might get a horse which was a distinct grunter, but when they galloped him he seemed to be perfectly sound. High conditioned horses for show purposes often make a noise to a stick. One gentleman made a reference to strangles as being not a disease of the respiratory organs. He could not agree with that, because it had been pretty well proved that strangles was a bacterial disease which attacked the respiratory gland.

Prof. DUNCAN said that with regard to the aspect of heredity, Prof. Craig's paper was marked with a caution characteristic of his countrymen. He had chosen ground for battle and wished to hold up the position he had chosen. The part that heredity played in this case seemed to be one of interest. Prof. Craig had said that the disease was undoubtedly hereditary, and he thought many would bear that out. If heredity was of the nature of predisposition it seemed to be very vague. He did not know exactly what predisposition was in the case of heredity. How could a horse be predisposed to strangles or influenza?

Mr. McKENNY was pleased that the Chairman had allowed them to speak a second time in this discussion. Prof. Craig had asked them to define the sounds of whistling and roaring, but each of us unfortunately formed our own opinions as to the sounds, therefore, at present it would be impossible to give a definition that would be generally accepted as correct, all we agree to is that the sounds are abnormal, as for instance the Professor in his paper set forth that in true whistling the abnormal sound was always in the inspiration, and all the speakers with the exception of one agreed with him, and that gentleman definitely said it was not always his experience, and he cited two cases that recently came under his observation, and told us that those two horses were very bad whistlers, and it was during expiration altogether that the abnormal sounds occurred. He also informed us that he performed the new operation on both of these horses, and when he opened their larynx in neither did he find any abnormality, and the arytenoid cartilages were quite active. Yet he stripped the ventricles of both horses and they became perfectly sound. Taking all that Mr. Magee had said into consideration, he (Mr. McKenny) was of the opinion that these horses were not true whistlers, and that the operation should not have been performed, and that they would have become sound equally as well without it. Under such circumstances a definition of the sounds of whistling, and many other matters pertaining thereto, could not be satisfactorily agreed on. Indeed each individual seemed to form his opinion at the time of examining a horse. Therefore, in considering the subject from a scientific and practical point of view, it is most essential to bear in mind that paralysis of the recurrent laryngeal nerve can arise from diseases of the lungs and stomach. Relative to the cases in which the new operation should or should not be performed, Mr. McKenny would have liked to refer to this matter, but as the Professor in his paper requested us on this occasion to confine our remarks to the questions which he had submitted, and not to introduce the subject of the operation. As to whistling being hereditary, Mr. McKenny was of the opinion that it undoubtedly was handed down from parents to their offspring, but in this age of enlightenment this state of matters is said to be predisposing influence and not heredity, all

because we fail to find the micro-organism of what used to be called hereditary diseases.

With most of Prof. Craig's remarks Mr. McKenny agreed, and he felt greatly indebted to him for the great trouble he must have taken in compiling the paper.

Mr. MAGEE said that speaking of the five-year-old horse which had strangles the vocal cords were working perfectly. In his opinion the horse became perfectly sound. If the arytenoid cartilage was sound the trouble must have been somewhere else. The explanation possibly was that the left or right vocal cord, after the horse had been galloped, either one or both of these cords became tired, and then they made abnormal sounds. That idea occurred to him before he met Prof. Hobday, and he said he considered that was the explanation too. As regarded the question, What is roaring and whistling? to answer that properly was practically an impossibility.

Prof. WILLIAMS, who was received with applause, in response to a request from the Chairman, said he considered it a great honour to be asked to speak on one of the most important subjects that the profession at the present time was wrestling with. As regarded the question, What is roaring? he thought he had the sympathy of the profession in saying that it was entirely an indefinite affection of the horse. Roaring to all of them was simply an abnormal sound which might be due to at least one of half-a-dozen or more affections. The expiratory sound was not to be classed with roaring. There was a sound which caused confusion with younger men than he saw there which was known as "high blowing." They could say a horse was a roarer and then proceed to find out what was the cause of his roaring. The cause might be removable, or a cause of roaring might be a matter requiring surgical interference. It might be perhaps the removal of tumour paralysis owing to a diseased bone or tooth, and unfortunately—and he said it advisedly—unfortunately though the profession had never laid down a hard and fast law what roaring was, they had come to the conclusion that when they saw a horse was a roarer he had a laryngeal affection. He differed from that. It was for the profession to lay down a correct definition of the term, or introduce a new term. Roaring meant so many things, and it was absurd for a man to say that because a horse roared it was unsound. One thus condemned a good horse which might be all right in a couple of days. He appealed to the profession to come to a definite definition of what roaring was, as he thought they knew the symptoms. As to what were the predisposing and exciting causes, he thought he had dealt with that. He was a strong believer in heredity with regard to roaring. In his own experience he knew a large number of cases in which one or other of the parents was unsound in wind, and the majority of the progeny became unsound in wind. If anyone brought a horse to him which had an unsound dam or sire and it grunted, if he were told that the parents were wrong in the wind he would not put the grunt down to stomachic affection, but as the premonitory condition of a permanent roarer. He appealed to the Association to seriously try and define the term "roaring," and get it generally accepted by the profession, so that with these transitory affections they should not condemn a horse as a "roarer," but have descriptive names for the afflictions.

Prof. CRAIG, in reply, said he thanked them very much for the kind reception they had given to the paper. His chief reason for writing on roaring was to glean information, and the information he wanted and had obtained was as to what the profession in Ireland considered the disease to be. Horses had been put down as roarers and whistlers and been recommended for laryngeal operations—and why? Because presumably they had a disease of the larynx. Now he heard that any horse who made a noise from whatever cause was a

roarer or whistler. Could an operation be of service in all these cases? It was time an attempt was made to distinguish between these various diseased conditions causing abnormal respiratory sounds. He defined the terms roaring and whistling in his paper. No doubt from the point of view of examination for soundness it was important that abnormal respiratory sounds should be noted, and no horse making a noise should be considered sound, but when it came to the recommendation of horses for operations, then a selection should be made. He thought such a selection was necessary in order to prevent what appeared to be theoretically the most hopeful operation yet recommended for roaring and whistling as he defined it, from getting into ill repute and becoming unjustly condemned. He was sorry that some attempt had not been made by practitioners in Ireland to distinguish between the causes of these abnormal sounds in the respiration of a horse. He did not know that he had very much criticism to reply to, and the reply he had in most cases was to refer to the paper. Most of the points to which reference had been made had been noted there. He thought they were too apt to think that a disease which was considered by their predecessors to be hereditary was to be put down as hereditary once and for all, and they were to accept it and never question it again. That was why he wanted information on that point. There was, he was sure, plenty of information to be obtained from the practitioners there that night, but they seemed afraid to give it. With regard to Mr. Winter's definition of whistling which disappeared after a run, he thought he (Prof. Craig) must have referred to that sort of whistling in another way. He was told by Mr. Howard that recovery had taken place from roaring and whistling. But he presumed that he did not mean the roaring and whistling which was defined in the paper. No doubt cases did arise where an abnormal sound was produced, and after a time the inflammation disappeared and the horse became sound. These were the cases often put down as roaring and whistling. Occasionally recovery did follow true roaring and whistling. He had heard of horses being sent abroad and recovering. Plenty of instances were given in which the progeny of these whistlers or roarers taken to South America say, or to California, and yet the progeny did not become affected. He was very much interested in what Mr. Magee had to say. He could not explain by the operation the recovery in the case he referred to. He referred to grunting. Some grunters might become roarers, and others remain perfectly sound.

Mr. MAGEE: Where does the grunting come from?

Prof. CRAIG: The larynx.

Mr. MAGEE: What part of the larynx?

Prof. CRAIG: The glottis.

Prof. Craig, continuing, said with regard to the horse mentioned by Mr. Healy, he would like to know what was the nature of the sound produced, whether it was made during inspiration or expiration. He hoped that at the next meeting, when the discussion would be continued, that the practitioners would come forward more readily to give their considered opinions and experiences on this important condition. Up to the present apparently sufficient care had not been taken in the selection of cases for removal of the laryngeal ventricles, and it was right that they should consider which cases should, and which should not, be operated on.

In conclusion, he thought it was hardly fair to the new operation that all horses making abnormal respiratory sounds should be operated on or recommended for the operation. (Applause.)

Mr. McKENNY proposed a vote of thanks to Prof. Craig for his very able and interesting paper. He deserved a second vote of thanks for his very clever reply to the speakers, indeed it was the keynote to the whole

subject, and if the matter were taken up and considered on the lines set down by Prof. Craig, he was certain that before long the profession would have more exact and definite knowledge of the subject of whistling and roaring which has been, and is at present, a subject of endless differences of opinions to professional men.

Mr. WINTER seconded the motion, and remarked that it was impossible to give a definition on paper of roaring and whistling. The paper had provoked a most interesting discussion, and he hoped it would be continued on a future date. (Hear, hear.)

The vote of thanks was passed, and the Chairman in conveying it, said that the discussion would be resumed at the next quarterly meeting when they had had time to read the paper in print. He thought it would add to the effect of the discussion if at the same time the results of operations performed on horses, suffering from roaring were given.

On the motion of Prof. Williams a vote of thanks was passed to the President for his conduct in the chair.

The meeting then terminated

Hydrophobia from Fox Bite.—Death of a Master of Hounds.

An extraordinary case of death from hydrophobia, caused by the bite of a fox, was investigated on Friday, Sept. 22, at a coroner's inquest upon the body of Mr. Richard Bower, of Crockerton, Warminster, the master of the South and West Wilts Foxhounds. The inquiry was held by Mr. F. A. P. Sylvester, the coroner for the district, at Sutton Veny, near Warminster.

From the evidence of a relative it was clear that some months ago Mr. Bower was bitten on the hand through a thick woollen glove by a hunted fox at the end of a run at the close of last season. Mr. Bower dismounted from his horse to break up the fox, and as he drove back the hounds and held the fox he was bitten by the animal. A hunt servant who was present at the time stated at the inquest that Mr. Bower made no complaint then about the bite. Later, however, Mr. Bower mentioned the matter casually to friends.

Medical evidence was given by Dr. Robert Lewis Willcox, who attended during the last illness. Mr. Bower, he said, became ill on Monday and died on Thursday night 21st inst. Not until Wednesday evening at six o'clock—twenty-eight hours before death—were any signs of hydrophobia manifest. Then, however, the symptoms showed, and the patient suffered from fever and great weakness.

It was almost impossible for him to swallow, and he had great difficulty in breathing. Paralysis of the muscles of the jaw ensued, with paroxysms. The patient suffered terribly. In conjunction with three other medical practitioners Dr. Willcox was convinced, after his clinical examination, that the complaint was hydrophobia.

During the interval between the time he was bitten and his death Mr. Bower had been in excellent health. No signs of hydrophobia have been displayed among the hounds, none of which were bitten by the fox, nor is there as yet reason to believe that other foxes in the district have been infected.

Specimens of the patient's secretions have been sent for examination to two eminent pathologists in London. *Daily Mail.*

I hold every man a debtor to his profession; from the which as men of course do seek to receive countenance and profit, so ought they of duty to endeavour themselves by way of amends to be a help and ornament thereunto. (Bacon).

P. B. Riley to be Lieut. (on probation). Dated Sept. 23.

CORRESPONDENCE.

AN UNUSUAL SKIN AFFECTION IN CATTLE.

Sir,
Reading in *The Veterinary Record* of last week, I see Mr. Wallis Hoare describes an outbreak of a skin affection which has certainly puzzled me as to its origin. I have had two herds affected. One which originated in a herd of 15 heifers, of from 2½ to 3 years of age, and they showed the symptoms described by him; but in most cases the disease was more severe. The point of inoculation seems to be the back of the knee. Extensive swelling from the knee upwards, and an abscess forms at the point of the shoulder in one out of three cases. The complaint spread to 40 beasts, varying from 18 months to 2 years, and

not only did they have the forelegs affected, but also broke out in the joint of the hock. All these cases showed loss of flesh, until the abscess broke and discharged.

The second outbreak occurred on a dairy farm, 15 miles apart from the first. In this case the means of inoculation were quite feasible. The owner having bought a heifer which had shown signs of an eruption at the back of the knee. In ten days four out of twenty milch cows had an eruption there, but in a much smaller degree to the others in the first case. After fourteen days the whole herd was infected. I treated them with antiseptic dressings and isolated them by not allowing any to be sold. It appeared to be a case of contagious malleanders and sallenders.

In conclusion, there is no doubt it is very contagious. No loss of life, but loss of value owing to the animals sinking in flesh. Perhaps some of our more fortunate confrères with bacteriological facilities can help us. Both these cases were reported as suspicious foot-and-mouth disease.

OSBORNE G. HILLS, M.R.C.V.S.

Royal Leamington Spa. Sept. 26.

DISEASE IN PIGS—AN ENQUIRY.

Sir,

I wonder if any of your readers could, by my simple description, tell me the malady from which quite a number of young pigs are suffering.

A litter of nine, a fortnight old, all died exhibiting extreme peeling of the skin. I have now under my observation another litter showing the same symptoms, and they look like dying.

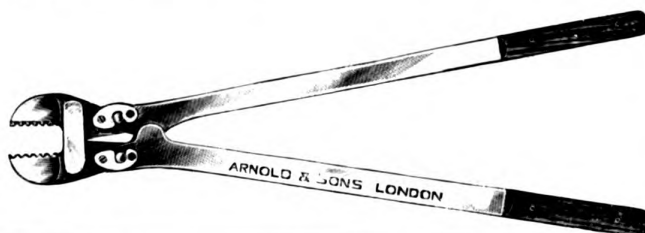

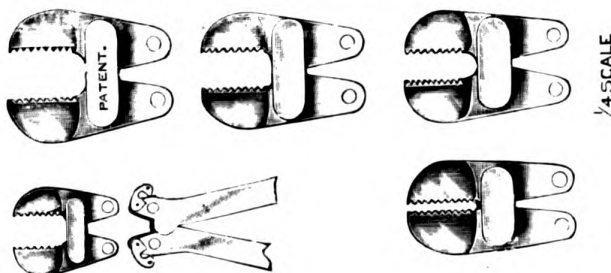

I should be grateful if anyone would give me the benefit of his experience.—Yours faithfully,
Sept. 28.

Practices for Disposal

GOOD-CLASS General Practice in first-class sporting district in the South Midlands, represented as returning between £450 and £500 p.a. is for disposal under satisfactory reasons. Further particulars in confidence will be given on application.

OLD established practice is for immediate sale, vendor having obtained an appointment. Situate in the Eastern Counties. Good agricultural district. Returns represented as being £450 p.a. C.C. inspectorship. Excellent house and stabling. Two acres of grass paddock. Price, in order to secure quick sale, £300, to include drugs, fittings, instruments, trap and cob.

AN exceptional investment for a smart man desirous of South African Practice. An opportunity of securing a partnership in an excellent equine and canine practice, established for 18 years. Represented as returning on average for last three years over £1000 p.a. Letter just to hand states: returns for first 6 months this year have been £607 10s., and that this is capable of great increase. Capital required (to include half-share of practice and valuation of surgery) under £600. References exchanged. Further information will be given to bona-fide applicants.

Wanted

PARTNERSHIP, with view to succession, in a good-class sporting practice, desired by an experienced M.R.C.V.S. with capital at command. Good horseman. Particulars will be received in strictest confidence.

LONDON, E.C.

PRACTICES FOR DISPOSAL

WEST OF ENGLAND. Town practice held nearly 20 years by present incumbent. Receipts: 1910 £1172. Contracts produce £251. Good house containing 5 bedrooms, 3 recept. etc. garden, stabling. Working expenses light. Premium £1500.

LONDON, W. Good-class practice returning about £600 per annum, with forge the gross returns from which are stated to be about £1000 per annum. Working expenses are exceptionally low. Convenient, well-situated house, rent £70 inclusive. Forge rent £69. Contracts produce about £300 per annum and could be greatly increased by practitioner willing to accept lower fees. Premium £1000.

WEST OF ENGLAND. Practice in good breeding and hunting district, returning £600 per annum. In present hands 10 years. Convenient house with surgery, stabling etc., rent £55. Premium one years purchase.

SOUTH COAST. Country practice returning about £835 per annum, including appointments producing about £70. In present hands 24 years. The practice has been worked by an assistant who would remain if desired. Convenient house, rent £21, larger available if required. Premium £800.

IRELAND. Partner wanted to take charge of practice returning about £1200 per annum. Rent of premises £82 per annum inclusive. Contracts produce over £400 per annum. Practice has been in present hands 12 years. Premium required for half-share £500.

HEALTH RESORT. Practice returning £650 per annum, chiefly dog. Good house with large yard, stabling, kennels, etc., rent £85, or would sell freehold. Premium £750. Valuation optional.

LONDON, N. Very old-established practice returning about £1200 per annum. Good house and thoroughly convenient premises, rent £90. The practice is principally horse. Receipts are increasing. Premium one years purchase. This practice is well-known to us and can be recommended.

LONDON, S. Practice producing over £1000 per annum. In present hands nearly 40 years. Good house, with stables, kennels, etc. rent £70. The practice is principally dog with some horses and dairies. Vendor retiring. Premium one years purchase.

SURREY. Rapidly increasing, well-established practice returning about £1000 per annum. Small house with stabling, kennels, etc. Capital required, including valuation, will be about £1300. The practice is well-known to us and can be thoroughly recommended to a suitable man.

HIGH-CLASS mixed practice returning about £650 per annum. Good premises would be let on lease or sold if preferred. Premium £600.

SEASIDE. SOUTH COAST. Partner wanted in practice returning nearly £700 per annum, and capable of great increase. Incoming partner must be good allround man. Premium for half share £300.

ROYAL COLLEGE OF VETERINARY SURGEONS. Fellowship Degree

NEXT Examination December 2nd, 1911.
Theses to be received November 4th, 1911.
Particulars on application to the Secretary, R.C.V.S.
10 Red Lion Square, W.C.

Victoria University of Manchester Diploma in Veterinary State Medicine

THE classes for the above will begin on Friday, Oct., 6th, at 3 p.m., at the Public Health Laboratory, York Place. Entries for the course should be made at the Laboratory not later than Oct. 6th. Further particulars may be obtained from the Director of the Laboratory.

Association of Veterinary Officers of Health

THE Annual Meeting of the above Association will be held in the Caledonian Station Hotel, Princes Street Edinburgh, on 13th October, 1911, at 10 a.m. The following papers will be read: "Tuberculosis and the Milk Supply," by Prof. Delépine, Victoria University, Manchester. "Existing and Prospective Legislation re Milk Supply," by John Lindsay, Esq. Solicitor and Town Clerk Depute, Glasgow. The discussion will be opened by J. S. Lloyd, Esq., F.R.C.V.S., D.V.S.M., Veterinary Officer of Health, Sheffield.

Members of the profession holding public health appointments are invited to communicate with the Sec.

A. M. TROTTER, M.R.C.V.S.,
Moore Street Abattoir, Glasgow.

For Sale

PRACTICE in best breeding district in Cumberland. Been in family nearly fifty years. No opposition. Good introduction given. Full particulars on application Address, 1101 V.R., 20 Fulham Road, London, S.W.

As Assistant

A GERMAN Veterinary Surgeon with best references wants a situation as assistant until he masters the language, au pair or on small terms. Reply under I.A. 6644 to Rudolph Mosse, Berlin S.W. 19.

Wanted.

ASSISTANT, to live out, wanted for town practice (horse and dog). State age, experience and salary required per annum. Address, 1103 V.R., 20 Fulham Road, London, S.W.

Manager

WANTED, manager for country practice, cyclist preferred. Address, 1107 V.R., 20 Fulham Road, London, S.W.

Mallein and Tuberculin

MEMBERS of the Profession may obtain Mallein and Tuberculin on application to the Principal, Royal Veterinary College, Camden Town N.W., on the following terms: in bottles, 6d. per dose. Minimum quantity supplied, two doses. In hermetically sealed tubes, containing one dose each (specially suitable for use abroad) 1s. per dose.

City of Liverpool

Assistant Veterinary Superintendent

THE Health Committee of the Council of the City of Liverpool invite applications for the appointment of Assistant Veterinary Superintendent, post graduate man preferred, at a salary of £200 per annum. The age of candidates must not exceed 32 years. The gentleman appointed will be required to devote his whole time to the duties of the office, and, will be required to sign an agreement to the effect that he holds the office subject to compliance by him with the Standing Orders of the Council. Applications, accompanied by copies of not more than three testimonials, endorsed "Assistant Veterinary Superintendent" and addressed to the Chairman of the Health Committee, under cover to the Town Clerk, Municipal Offices, Liverpool, must be delivered at the Town Clerk's office, not later than 10 o'clock, a.m., on the 10th of October, 1911.

Canvassing of Members of the Council will be regarded as a disqualification.

EDWARD R. PICKMER,
Town Clerk's Offices, Liverpool, Town Clerk,
27th September, 1911.

As Assistant

BY M.R.C.V.S., (1909), aged 25, assistantship in large mixed practice. Practical, sober, industrious. Excellent testimonials. Address, 1102 V.R., 20 Fulham Road, London, S.W.

As Assistant

SON of V.S. aged 26, desires post in good mixed town and country practice, experienced in routine veterinary work, has taken charge. Energetic, good dispenser and book-keeper; ride, drive and cycle, references, disengaged Oct. 28. Andrews, 89 Horninglow Rd., Burton-on-Trent

Wanted

EXPERIENCED veterinary surgeon as assistant in large mixed practice, must be well up in all branches and thoroughly practical. Apply, stating age, and salary required, to 1106 V.R., 20 Fulham Road, London, S.W.

All communications respecting advertisements should be addressed to

H. & W. BROWN, 20 Fulham Road, London, S.W.

Tracheotomy Tubes

MISS JONES, successor to F. B. Jones, M.R.C.V.S., still continues to supply the Special Tracheotomy Tubes patented by her late father. Special terms to Veterinary Surgeons. Address, 86 Kimberley Road, Leicester.

To Veterinary Surgeons

ADVERTISER, ex-student with extensive experience, well up in all branches, wishes to join veterinary surgeon in or near London and assist him in his practice. Single: live in or out: terms moderate. Address, 1104 V.R., 20 Fulham Road, London, S.W.

To Veterinary Surgeons

M.R.C.V.S., qualified 1906, good experience of all branches of the profession, requires position as partner or manager, with view to early succession. Address, 1105 V.R., 20 Fulham Road, London, S.W.

For Disposal

ESTABLISHED practice in manufacturing town, Midlands: horse and canine: good house and kennels, working expenses small. Moderate capital required: introduction would be given. Could be greatly increased. Address, 1108 V.R., 20 Fulham Road, London, S.W.

For Sale

SMALL practice, all canine, in good-class London Suburb. Owner has never entertained horse practice, but it can be done. Nearest competitor three miles. Address, 1109 V.R., 20 Fulham Road, London, S.W.

For Disposal

GENUINE, old established town and country practice doing nearly £600 a year. No forge. Worked with small car. Three months introduction. Present practitioner retiring. Price, with good stock of drugs £325. Surgery fittings, instruments etc. may be taken at valuation. Address, 5110 V.R., 20 Fulham Road, S.W.

Assistant Wanted

IN a good mixed practice. A gentleman wishing to take the post graduate course at Manchester University could have special facilities for study. None but good men need apply. Address, 8110 V.R., 20 Fulham Road, London, S.W.

Wanted

M.R.C.V.S. practical and experienced requires engagement as manager. Locum or assistant. Good references. Address, 6110 V.R., 20 Fulham Road, London, S.W.

Practice Wanted

GOOD mixed or country practice wanted at once: North-West (Eng.) or Midlands. Cash settlement. Address, 7110 V.R., 20 Fulham Road, London, S.W.

AGENTS REQUIRED in unrepresented districts for the **IMPERIAL ACCIDENT INSURANCE CO., LD.** Est., 1878. Horses Insured against Death from Accident or Disease, Mares for Foaling and Loss of Foals; Farmers' Liability for Accidents to Labourers, Servants, and Workmen's Compensation. Claims paid, £500,000. Address Agency Manager, 17, Pall Mall East, London, S.W.

Wanted

ASSISTANTSHIP (or locum) by **M.R.C.V.S.**, thoroughly practical and reliable, experienced in town and country practice, good references. Address, 'Locum,' c/o Golding & Perry, Veterinary Infirmary, Eastbourne.

Branch Manager or Locum

PRACTICAL M.R.C.V.S. would act as above, wide experience in all kinds of practice, not afraid of work, experienced horseman, light weight, reliable, good references. Address, W. Cureton, The Chance, Upton, near Birkenhead.

For Immediate Disposal

YORKS, North Riding. Wanted, reasonable offer. Receipts over £300, good house to go with practice. Rent £12. Good agricultural and breeding district. Present owner 27 years; no opposition; C.C. appointment: introduction given. Address, 5092 V.R., 20 Fulham Road, London, S.W.

Situation Wanted

RESPECTABLE young man with experience of dispensing, veterinary work and book-keeping, requires position. Terms moderate, total abstainer. Address, 5095 V.R., 20 Fulham Road, London, S.W.

Qualified Assistant Wanted

MARRIED, to manage a branch practice, must have good references. Address, 5096 V.R., 20 Fulham Road, London, S.W.

For Disposal

WARWICK, freehold house, 20 Jury Street. Veterinary surgeon's business carried on upon premises for over 50 years, in main street, country town, good hunting district. 3 reception, 6 bedrooms, bath, large yard in rear. 5 loose boxes, stall, large shoeing forge, saddle room, loft, surgery. Possession to day. Ledbrook, Solicitor, Warwick.

As Manager, Assistant or Locum

QUALIFIED veterinary surgeon, experienced both town and country, wishes post as locum, manager or assistant, indoor or out. First-class references. Address, 5097 V.R., 20 Fulham Rd., London, S.W.

For Disposal

OLD established country practice, unopposed by motors returns average over £300 per annum. Address, 5098 V.R., 20 Fulham Rd., London, S.W.

Partner Wanted

IN old established horse and dog practice, on the South Coast, average returns £650. Price for half-share £300. Easy terms may be arranged. Address, 1509 V.R., 20 Fulham Road, London, S.W.

Open for Engagement.

M.R.C.V.S., well up in town and country practice, excellent credentials, open for engagement any kind. Good operator. Locum, 79 Millbrook Road, Barrington Road, Brixton, London.

Assistant Wanted

FOR horse and dog practice near London. Full particulars, etc. Live out. Address, 4099 V.R., 20 Fulham Road, London, S.W.

Wanted

INDUSTRIOUS, reliable young man to assist in branch practice, Sussex. Able to cycle. References required. Address, 1309 V.R., 20 Fulham Road, S.W.

"MAGNUM" PESSARIES.

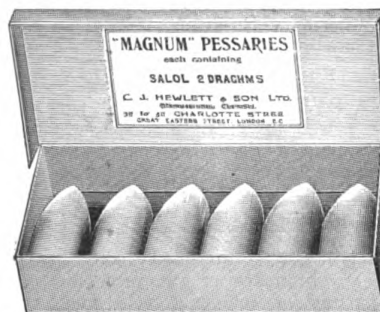

(HEWLETT'S)

"Magnum" Pessaries are prepared with a medicated non-oily base which is both effective as a Uterine Antiseptic and of special benefit in Parturition both in Cows and Mares.

A "Magnum" Pessary should be inserted directly after parturition in order to maintain the Uterus in a healthy state. It can be inserted with the greatest ease and will keep the parts in a thoroughly antiseptic condition for a lengthy period.

Alkaline "Magnum" Pessaries have recently been recommended to neutralise excessive acidity of Vaginal secretion.

"Magnum" Pessaries are supplied according to various formulæ as below, and Veterinary Surgeons' own formulæ can be made up as required.

		Doz.	12 doz. @	Doz.

THE VETERINARY RECORD

A Weekly Journal for the Profession.

EDITED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1213.

OCTOBER 7, 1911.

VOL. XXIV.

THE INAUGURAL ADDRESS AT CAMDEN TOWN.

The Camden Town School opened its doors on Monday last, when those who attended—including a larger number of visitors than usual—heard a very interesting address. As might have been expected, Mr. Stockman made many references to his own branch of veterinary work—preventive medicine, but he also devoted much attention to veterinary education, and in this respect the paper departs a little from the beaten track. Usually such addresses, so far as they relate to instruction at all, are largely concerned with that of the still unqualified student. This one is mainly taken up with the wider question of post-graduate study. More methods than one of pursuing this, as Mr. Stockman pointed out, are open to the veterinarian. One or two are only recent acquisitions; others are of older standing; but scarcely one is yet fully appreciated by the profession.

A set post-graduate course, such as the now famous one at Camden Town, is the method that will probably always attract most qualified students. So far these courses have been confined to veterinary pathology and sanitary science, but there is no reason why similar courses, including medicine and surgery, should not be instituted for the benefit of practising clinicians. Mr. Stockman, however, dwelt at some length upon an older method of post-graduate study which has much to commend it—an independent and largely self-directed course at any large veterinary college. We could name well-known veterinarians who have done this with the best results, long before post-graduate classes were instituted; and one of its great advantages is that the periods and subjects of study alike can be modelled to meet the individual case. This feature will always commend it to the serious student, who will probably find this method the best of all.

Mr. Stockman mentioned one other post-graduate facility which is only just opening to our profession—research scholarships to enable men to train as investigators. Thanks to the Board of Agriculture, a good number of such scholarships are now to be open to veterinary graduates; and some of our younger men may be trusted to obtain distinction in them.

Mr. Stockman takes a roseate view of veterinary work as a whole: but there is no doubt that he is right in saying that the prospects it offers to those who choose its preventive and research side were never so bright as at present. Some of our old functions are undoubtedly declining. This new one, although it is already absorbing many of best graduates, is only beginning to open to us.

VETERINARY WORK IN THE PUNJAB.

The Annual Report of the Punjab Veterinary College and the Civil Veterinary Department, Punjab, for the year 1910-11, is, unfortunately, shorter than usual. For some reason it has been ordered that its text should be reduced from that of former years; although the work it concerns is expanding, and the publication really comprises two separate reports of different institutions. That of the Punjab Veterinary College, of which Major Smith is Principal, has been written by Mr. S. H. Gaiger, I.C.V.D., the Officiating Principal; that of the Civil Veterinary Department is by Mr. V. de V. H. Woodley, its Chief Superintendent; while a note upon both by the Director of Agriculture precedes them.

The Punjab College is on the eve of a great change. Government has decided that it shall be enlarged so as to serve as the sole veterinary college for all Northern India; but nothing has yet been settled regarding the details of the change. Plans of requirements are being prepared; and it may be hoped that a definite scheme may be adopted and set on foot during the present year. It seems most likely that this will take the form of building an entirely new and larger college upon a fresh site not far away from the present one.

In the meantime the work of the existing college is inevitably more or less unsatisfactory. The examiners' report lays stress upon the grievous overcrowding of students, instancing the fact that the anatomy class contained 77 men, while the dissecting room appears suitable for no more than 16 or 20. In fact, the College is reducing the numbers of its students in order to gain in teaching efficiency; and of course this will mean shortening the supply of native graduates, which already does not cope with the demand for them. There could be no clearer proof of the need for a larger college and staff.

Despite these disadvantages, the year's work seems to have been very good. All things considered, the examination results certainly are so; while some important research work, which will be reported upon separately, has been done during the period. This includes the discovery of a new form of Indian bovine trypanosomiasis, which is only demonstrable by cultural methods; and of a form of canine piroplasmosis which is unaccompanied by jaundice, is unaffected by the trypanblau treatment, and is therefore possibly due to a new species of piroplasm.

Mr. Woodley's report of the Civil Veterinary Department is also very satisfactory in many respects, perhaps most of all in its evidence of the success of

the local veterinary hospitals. During the year under report there were 102 of these in the province, as against 94 in the previous year, and their attendances show marked increase. "The average daily attendance at each hospital works out at 16, and the average daily admission of fresh cases 7.5; the figures for last year being 12.95 and 5.8 respectively." These figures speak for themselves.

Breeding operations continue to make headway, if somewhat slowly; while there is a great reduction in most of the animal epidemics. Altogether, during the year, only 217,823 cases of epidemic disease were reported, against 337,146 the year before. Foot-and-mouth disease in particular has decreased enormously, only 83,960 cases being reported against 247,423 for the previous year.

Most of the other epidemics also show more or less reduction, with the very important exception of rinderpest, which has risen greatly. During the year 99,126 cases of rinderpest were reported, against 48,226 for the year before. Fortunately it has been possible to greatly increase the number of preventive inoculations upon in-contact animals; 102,603 have been inoculated, against 43,250 last year, and only 300 deaths occurred after inoculation. Native opposition to inoculation, though still marked in some districts, is evidently subsiding; and the results of this year's inoculations will certainly weaken it still more.

The result of the whole year's work goes to show that the Veterinary College and Civil Veterinary Department of the Punjab, both alike, undermanned, and handicapped in many other directions, are both rendering invaluable service to the agriculture of the province. The work of both is expanding rapidly; and we are glad that facilities for expansion are at last to be given to the College. Such facilities are also being given to the Veterinary Department, but these seem insufficient for its growth. Eight veterinary assistants were added to its staff during the year under report; but during that period the work evidently increased so much that more must now be necessary.

TETANUS SUCCESSFULLY TREATED WITH MAGNESIUM SULPHATE.

By W. A. DYKINS, M.R.C.V.S.,
Government Veterinary Surgeon, Umtata, S.A.

Having recently read in *The Journal of Comparative Pathology and Therapeutics* an article by Capt. W. O. Dawson, A.V.C., on results obtained from the above treatment, I was fortunate in meeting a case of tetanus shortly afterwards, and applied the same treatment with good results.

During a visit to Port St. John's, which is one of our sub-districts, the Government Stock Inspector informed me of a beast sick at a trading station twelve miles from the village, the malady he diagnosed as lockjaw. I immediately instructed him to proceed there and apply the treatment.

I arrived at the station two days later and confirmed his diagnosis.

History.—The heifer calved on the 14th of August normally, but retained the cleansing for a few days, which was afterwards removed by the natives, who had some difficulty, and ignored anti-septic precautions. She had been noticed sick about seven days before my arrival, and had had two injections of Mag. sulph.

Symptoms.—The beast was standing in a kraal, exhibiting great distress and assuming a rigid posture, its head extended, and its tail straightened and slightly elevated. Great weakness was noticed; animal would lie down and unable to rise without assistance. Trismus had been severe, but showed improvement, muscles of neck, chest, loins, and limbs showed tonic spasms, and were very tense. The nostrils dilated, and the protrusion of the membrana nictitans over the eyeball was exceptionally well marked. Animal showed accentuated reflexes. Breathing and pulse accelerated, temperature normal, obstinate constipation was observed.

Treatment.—The beast was allowed to remain in kraal, as there was no building or shed available. Up to the present she had received 2lb. of salts from the owner, and two subcutaneous injections of a saturated solution of Mag. sulph. 40 c.c. daily (20 c.c. on each side of neck). These injections were continued for a few days later. I had a letter from the Stock Inspector on September 5th informing me that the beast was making an excellent recovery, feeding well and able to walk about.

As tetanus is somewhat prevalent in this district, and the mortality high, I hope to be able to put this treatment to a more thorough test in the future.

DIGESTIVE DISEASES OF RUMINANTS.

It is not because I have any desire to pose as an authority on the diseases of the stomachs of ruminants that I venture to put on paper a few thoughts in reply to Mr. Hoare's questions contained in your issue of the 26th August last, but that the subject is very interesting, and cases are often very puzzling, if one endeavours to arrive at anything like an accurate diagnosis.

Does impaction of the omasum occur as a disease *per se*? I do not think that impaction of this stomach does take place as a distinct disease—if by impaction is meant the over distension of the stomach with food, whether in a moist or dry state; but I do not accept the idea that this stomach is never affected with disease except as the result of disease affecting the other stomachs. I believe it is subject to primary disease and nearly as frequently as the others, only to describe the commonest disease of this stomach accurately it should be named desiccation of the contents of the omasum.

The situation of this stomach in the ox renders it peculiarly liable to such a condition; the greater, if not the whole bulk of this stomach is situated above its entrance and exit, so that to keep its contents moist liquid must travel, or be forced, more or less uphill. When this stops from any cause, or the supply of liquid is cut off, the tendency will be

for the liquid that is present between the leaves to drain away, and unless the walls of the stomach happen to be paralysed, this will be materially assisted by the normal contractions of the organ.

Is not this stomach's separate nerve supply an endeavour to throw it out of gear as much as possible with the other stomachs, and so render it less liable to be influenced by their diseases, since its own structure and situation render it so liable to disease itself?

Impaction of the omasum is not always associated with brain symptoms, and should not be called stomach staggers. Stomach staggers is a symptom of the absorption of some poison produced in the stomachs during the process of digestion, or decomposition, of certain foods, and may be associated with desiccation of the omasal contents, or with gastritis.

Causes.—Sudden change on to very succulent food produces it by stimulating the walls of the stomachs to increased movements, which in the case of the third stomach tends to force the liquid contents of that stomach out, and also tends to draw more liquid from the third into the fourth stomach.

Seeds of over-ripe grasses cause it by being taken out of the rumen with the liquid overflowing from it, but as they carry little water in their structure, and, being hard allow the water surrounding them to percolate freely, they act as desiccants; some of them also produce poisons which have a paralysing effect on the stomach either through the local or central nerve supply.

Allowing cattle to lick dry meal without providing a sufficient supply of water causes it, because of the amount of fluid the meal absorbs. In a case of this kind the omasum may give one the impression that it is larger than normal from being impacted.

Systematic under watering will act as a cause.

Simple inertia of the stomach from the prolonged action of cold or any other disturbing factor might also produce it. It is occasionally produced by prolonged parturition; in this case it is due, I think, to the pressure exerted during the throes of labour pressing out the liquid contents of the stomach.

I would suggest that a slaughterhouse is not the best place to examine the stomachs of ruminants for normal conditions, as the animals there may have travelled long distances, and been deprived of both food and water for considerable lengths of time.

Symptoms.—If it arises as the result of sudden changes on to succulent food there is generally some diarrhoea to begin with, which is not very severe, and soon gives place to very obstinate constipation, unless attended to early. When it arises from dry feeding the animal is usually noticed by the attendant not to be quite so ready for its food as ordinarily for a day or two, and this ends with the animal by and by refusing all food, although the bowels appear to be acting normally. The illness about this time is generally attributed to the effects of a chill, since the animal is dull, the coat more or less staring, possibly an occasional slight quiver

about the flank, and a slight quickening of the respiration may be seen. There is no grunt. A careful examination reveals that the first stomach is a little more sluggish in its movements than normal, and that there are no sounds, or only very faint ones, over the seat of the third and fourth stomachs. If a dose of medicine be given at this stage, it will be found that before it has time to act all motion from the bowels will have ceased for a matter of twelve hours or so. If no medicine be given about the time indicated, but its administration is delayed, as it very often is, for another twelve hours, there is then no motion from the bowels, no movement at all in the third and fourth stomachs, although the rumen is still acting; there is a grunt, more or less frequent and more or less painful according to the condition of the patient, and some restlessness due to abdominal pain. The grunt is always most evident when the animal is lying, and it may be so slight, when the animal is standing, as to be audible only when the ear is applied to the side.

There are also the usual signs of ill-health; uneven surface temperature, eye dull, conjunctival vessels a little injected, muzzle dry: the pulse is not much disturbed at first, unless in cases beginning with diarrhoea, but afterwards becomes frequent and faster than normal, but remains soft until the onset of inflammation; the temperature at first is normal, and remains so, or rises very little until inflammation sets in. When brain symptoms become manifest, you may get almost any nervous symptom shown, or the whole list of them may be gone through, to terminate in death either in coma or delirium. Once the contents of the omasum have become thoroughly desiccated, I do not think any medicine will soften them, or only in very exceptional cases, and should purgatives simply cause watery evacuations the case is generally hopeless, and the administration of large doses of purgatives worse than useless.

Gastritis. Gastritis is often the result of unrelieved desiccation of the omasum, and of overdosing with purgatives to overcome that condition, but it also arises as an independent affection, from causes which, in other subjects, would produce the previous disease, such as any sudden change of food, and the greater the change in the food the more liable is this disease to result; all irritants produce it, if taken in sufficient doses.

Symptoms. These are always severe, but unless there is desiccation of the contents of the omasum, or some other obstruction to the passage of the contents of the anterior stomachs, gastritis or gastro-enteritis is, I think, always associated with diarrhoea, and the more severe the inflammation the worse is the diarrhoea, until it becomes dysenteric, and towards the end nothing may be passed but mucus and blood.

The advent of gastritis, while attending a case of desiccation of the omasum, is heralded by a sudden change for the worse in all the symptoms shown by the animal, and even here diarrhoea may arise.

There is evidence of great abdominal pain, from the restlessness of the animal, almost up to the

time that the recumbent position is assumed from exhaustion, there is constant moaning—more than grunting; the eyes are sunk in the orbits, dull and listless, the belly becomes tucked up, and there is pain on pressure over the right hypochondrium—pressure here causes a painful grunt. There is grinding of the teeth. Fever is always present until near the end, and the pulse is frequent, small, and hard (wiry), the breathing is accelerated, and latterly the breathing becomes oral, more especially during expiration.

Impaction of the rumen. Cases of this disorder which recover do so, not so much from the direct action of the purgatives on the contents of the rumen as from their action on the other stomachs and bowels, keeping them in working order. The stimulants, which are also given in this disease, materially assist by acting on the rumen through the nerve supply. However, recovery is mainly due to the food in the rumen undergoing some form or other of digestion or fermentation, which reduces its bulk, by rendering some of it soluble, and enabling it to be removed in the liquid that is always passing from the rumen into the other compartments. The most reduced particles of the coarser food also get conveyed onwards with the liquid, and in some cases it is really wonderful what coarse material passes through the digestive canal before rumination is satisfactorily re-established. I do not think that the whole of the food partaken of by a cow at any time is put through the process of rumination, but only the coarsest particles of it; the larger part is sifted out between the rumen and reticulum, and passed on to the omasum without being ruminated at all.

Constipation of the bowels. From what is published in veterinary literature, one is almost led to believe that the only form of constipation which affects ruminants is that which is connected with their stomachs, and that there is no constipation connected with their bowels. Milch cows, at any rate, are subject to constipation of the bowels, which is associated with some functional derangement of the liver, during the latter part of writer and the early spring.

It appears to be due to changes in the food which occur about this time. The supply of roots fails or the roots become deprived of a part of their natural moisture and get very indigestible, and various additions are made to the food to compensate for these things, in an endeavour to keep up the supply of milk.

The animal is noticed to become gradually constipated in the bowels, the fæces become drier and drier, and more coated with mucus until the animal shows diminished appetite and reduced yield of milk; then the fæces are noticed to be scanty, and the urine high coloured; the extremities colder than normal, and rumination more or less suspended.

If the animal is not attended to now, the appetite fails entirely, defæcation and rumination cease altogether, and the milk yield stops; colicky pains put in an appearance—if they have not been manifest before—the animal lying down and rising fre-

quently, and kicking at its belly with the hind feet; lumps of yellowish-white mucus pass from the bowels, but movement in the stomachs never entirely stops.

The pulse is not altered at the beginning but when the disease has advanced to the point of diminishing the milk yield, it is often less frequent than normal, and slow, but quite full; the temperature is not altered any as a rule, but may be slightly below the average, while the mucous membranes and skin are tinged more or less yellow. Except colic be present, the respirations are not interfered with.

In this disease it is not difficult to get a reaction to purgatives, and once the bowels are opened the appetite improves immediately; but the constipation is very apt to return in a day or two, when the same set of symptoms become manifest. To prevent this a course of laxatives, with liver stimulants and tonics is necessary, together with an entire change of diet, if this can be attained at the season of the year when the disease appears. These cases sometimes take quite a long time before the natural functions are thoroughly restored.

PETER WILSON.

Lanark. Sept. 27.

ABDOMINAL COMPLAINTS.

By W. TART, M.R.C.V.S., Stoke-on-Trent.

I have been much interested in reading the various articles and letters on abdominal complaints of cattle, which have appeared lately in *The Record*. The article by Mr. Hugh Begg has been especially interesting to me. I am tempted, with much diffidence, to describe my own experiences with somewhat similar cases.

During the last ten years, as I usually pass a country knacker's yard on my daily round, I have made a rule of examining post-mortem the majority of cattle (chiefly milch cows) which have died under my treatment.

My clients, too, are very apt to regard the cases exhibiting such a train of symptoms as described by Mr. Begg, as occasioned by impaction of the omasum, and to treat them with a strong purgative, usually salts and treacle.

I must say that, although I have examined scores of cases I have never yet met a case in which I could definitely say death was due to impaction of the omasum. Further, I do not think that in any one of the cases did the trouble arise primarily in the omasum.

Putting aside those cases due to penetration of the stomach wall by a foreign body (which are fairly common in this district) I have found the most general causes to be

(a) Inflammation of the abomasum, sometimes affecting to some slight extent the other stomachs, and often extending to the bowels.

(b) Peritonitis, general or localised.

Those cases due to (a) I have found most common (although by no means confined to them) on a number of farms which border closely on collieries

and furnaces. On these farms the cattle generally do very badly, seldom lasting more than four or five years after the first calving. They are very liable to digestive troubles, arising, in my opinion, from the ingestion of mineral matter deposited on the grass from the smoke. I find that they almost invariably die if treated with drastic purgatives. They do much better after a mild aperient, followed by internal antiseptics, carminatives, etc. The post-mortem symptoms are those of gastro-enteritis.

I have been very sceptical as to peritonitis arising from chills to the abdomen. But I am inclined to change my opinion, as during the last few weeks, since the breaking up of the fine weather, I have had a number of cases which I have regarded as due to peritonitis, to which I am unable to assign any other cause. In some of these cases, in addition to the symptoms described by Mr. Begg, there was flatulence not of the rumen but of the abdominal cavity. The gas being in the abdomen itself, and the mass of the rumen easily felt a distance from the wall of the abdomen.

I will eliminate the cases which recovered, as the diagnosis may be open to doubt, and describe two typical cases which are fresh in my memory.

1. *Subject*.—Blue cow, had first calf a couple of months ago, was in moderate condition. She was noticed to be ill and shivery. The owner administered a purgative and sent for me the following day. I found her to be very depressed, eyes sunken, temperature 104, pulse frequent and thready, faces scanty but sloppy, abdomen tense, appetite entirely absent, not very thirsty, milk gone, grunting with every breath.

Diagnosis.—Peritonitis, with a saving clause that it might be "wire."

Treatment.—Quinine, digitalis, opium, calomel in hot beer three times a day. Gruel at frequent intervals. Had her well rugged up and kept warm. She died in a few days.

Examination post-mortem showed peritonitis (apparently not septic) more marked in the region of the diaphragm. Pleura and thoracic organs normal except the one lung congested on the side she had lain before death. A careful search for a foreign body was useless.

2. *Subject*.—Shorthorn cow, rather poor, had calved four months.

Symptoms.—As in former case, but grunting very heavily, abdomen very flatulent, temperature 105.

Treatment similar to first case. She too had had a purgative. Applied hot cloths to abdomen. On second visit she was clearly moribund, to satisfy owner I inserted a short trocar and canula and a quantity of gas escaped, but not so much as is usual in tympanitis of the rumen. I could feel that the instrument was not in the rumen. She died on the 3rd day.

Post-mortem showed severe septic peritonitis, both parietal and visceral, with a very considerable amount of fluid in the abdomen. The pleura was slightly reddened, lungs congested, no fluid in chest. After a most careful search (the owner was present) I failed to find any trace of a foreign body.

These cases arose suddenly, and if not due to chills I do not know to what cause to ascribe them. It may be, as Captain Rainey suggests, in his letter published in the issue of the 16th inst., they are caused by infection from the intestinal tract without a puncture. But they arose very suddenly and were ushered in by shivering and symptoms of a chill.

The most interesting symptom to me is the flatulence of the abdomen, usually regarded as an almost certain symptom of "wire."

A VICTIM OF QUACKERY.

A well-grown male cat, about six months old, was brought to our infirmary by its owner, who stated that four days previously it had been castrated, but he was afraid it had not been properly done. Examination of the patient showed his fears to have been well founded.

The method of castration adopted was simply to cut off the lower portion of the scrotal sac: with what object it is difficult to imagine, unless it was surmised that the testicles would fall out. On examination it was found that both testicles had descended, one to about half an inch and the other about three-quarters of an inch below the scrotal incision. They were considerably swollen and suppurating freely. Both cords were thickened and united together, and to the edges of the wound by numerous adhesions. The cat was very "mopey," and was stated to have partaken of no food since the "operation."

The adhesions were dissected away and the cords separated, but owing to their inflamed and thickened condition it was considered inadvisable to remove the testicles by the usual method of drawing. A ligature of soluble gut was placed round each cord, the testicles snipped off, and the wound thoroughly cleansed.

Next day the cat fed greedily, the wound healed without any further attention, and he was sent home in four days time.

"ERIN."

PROLONGED RETENTION OF FŒTUS.

During April of last year I was asked to attend at the parturition of a rather valuable Jersey cow, which had the previous year given birth to her first calf in an uneventful manner.

At the first visit there was no signs of immediate calving, but when attending about ten days later the usual symptoms were evident—enlarged udder, altered pelvis, etc.

The attendants and myself could feel the calf (or thought we could) on pressure of the right side, but after paying several visits to the cow it was a surprise to find parturition no nearer, and the signs of its approach were now less marked than before. There was no discharge from the womb, and the cow's general health was normal.

A week ago, eighteen months after the date due for calving, I was called again to see this cow. She

appeared in some pain and not in good health—a discharge like dirty mustard was coming from the vagina, and the attendant informed me that about a gallon of this material had been passed. Next day a foetus was expelled having the appearance of one carried about five months *in utero*.

It is, I know, not uncommon on post-mortem examination to find a mummified foetus in the womb of supposed "empty" cows, but the above phenomena are surely unusual.

It is certain that the last date of service was July 6th, 1909.

J. H. RIPLEY.

Hurst Green, Sussex.

ABSTRACTS FROM FOREIGN JOURNALS.

THE TEMPERATURE IN QUARTER-ILL.

It will be remembered that, some time ago, several European veterinarians published clinical observations which certainly seemed to throw doubt upon the classic view that a high temperature is associated with quarter-ill. Major F. S. H. Baldrey, F.R.C.V.S., D.V.H., I.C.V.D., has gone into this question at Muktesar, and has published his results in *The Indian Veterinary Journal*.

Maj. Baldrey's observations were made under peculiarly advantageous conditions. At Muktesar, a considerable number of animals suffering from quarter-ill are carefully observed; and the course of the temperature can therefore be followed with far greater accuracy than is usually possible in ordinary practice, where the temperature takings are necessarily few and irregular. Major Baldrey observed 21 animals in all; and in 3 of these the temperature was taken every two hours, while in the others it was taken morning and evening. The conclusion he draws is "that in black-quarter there is usually at some place in the course of the disease a high temperature, but to the ordinary clinician the absence of this would not be remarkable." If the temperature were taken every hour, he thinks it very possible that every case would show a high temperature at some period in its course. The temperature, however, varies from hour to hour, as three cases in which it was taken every two hours show. It commences to fall very rapidly immediately after reaching its highest point, and becomes very low just before death—sometimes descending to even 94° F.

Major Baldrey's 21 charts also show that the most acute cases are the least likely to show very high temperatures. In the more chronic cases which extend over a time of from two to three days, there is always a highly febrile period; while in very acute cases collapse seems to supervene almost at once, and the temperature quickly runs down until death.

These observations are so much more complete than the majority of those which are found possible in practice that they deserve to be widely known. Probably they represent the truth of the matter,

especially as they amplify and corroborate, rather than clash with, the results reported by others. They explain how it is that some practitioners have found normal or sub-normal temperatures so often as to conclude that quarter-ill is not a febrile disease. The truth appears to be that the disease is a febrile one, but the fever may be of such short duration that its absence is of no great diagnostic importance.

PRIMARY GIANT-CELLED SARCOMA OF THE HORSE'S SPLEEN AND ITS CONSTITUTIONAL RESULTS.

Edward Nyiri, of Budapest, records (*Allatorvosi Lapok*) the following pathological observation. A horse's spleen, measuring 52 centimetres (20 4-5th inches) long by 28 centimetres (11 1-5th inches) thick, and weighing 7,260 grammes (roughly about 16 pounds) was sent to the Budapest Veterinary School for examination. The horse from which the spleen had been taken had been extremely emaciated, but no pathological lesions had been demonstrable except in this single organ.

The surface of the spleen showed numerous roundish protuberances, ranging from the size of a bean to that of a child's head. When incised, the cut surfaces of these swellings showed grey-red spots, while the cut surface of the spleen appeared brown-red.

Microscopic sections cut from these swellings stained unequally, and some portions remained quite uncoloured. The capillaries were greatly dilated. The cellular substances of the swellings showed two kinds of cells. Cells of the one kind were larger than ordinary lymphocytes, and possessed a nucleus which was poor in chromatin and was surrounded by a broad zone of protoplasm. Cells of the second variety showed only a very thin streak of protoplasm, and their nuclei were rich in chromatin and showed different forms of division. In much smaller number and only at isolated places larger cells were noticed, the protoplasm of which stained dark red with hæmatoxylin-eosin and showed smaller roundish unstained portions (vacuoles). The nuclei in these large cells were rich in chromatin, and two or several nuclei of round, oval, or elongated shape, could be counted in one cell. Lastly, in isolated groups, eosinophilous cells were noticed, the nuclei of these being poor in chromatin and small. The ground substances of the tumours consisted of connective tissue, which was rich in blood.

The microscopic findings, therefore, indicated that the tumour was a lympho-sarcoma or lymphocytoma containing giant cells. The neoplasm arose from the malpighian follicles, and the author ascribes a two-fold action in causing the emaciation of the horse to its agency. In the first place, its growth had caused a permanent pressure upon the neighbouring structures. In the second place, the toxic materials which arise in such cases had also played a part in causing marasmus.—*Berliner Tier. Woch.*

W. R. C.

BOARD OF AGRICULTURE AND FISHERIES,
4 WHITEHALL PLACE, LONDON, S.W.

October 3rd.

The Board of Agriculture and Fisheries desire to draw attention to the fact that in times of great prevalence of foot-and-mouth disease on the Continent there is a grave risk that the virus of the disease may be imported indirectly into Great Britain. During the nine months of the present year the infection of foot-and-mouth disease appears thus to have been imported on no less than five occasions, and inasmuch as the disease is still very prevalent on the Continent of Europe, it seems probable that the risk of its re-appearance in Great Britain will continue to exist for some time. The Board are gratefully cognizant of the valuable assistance they have received from the veterinary profession in the past, and they recognise the difficulty in which practitioners and inspectors are sometimes placed when suddenly called upon to decide promptly whether or not the disease is present, since, in spite of its exceedingly contagious character, it has recently appeared under circumstances in which no connection with a previous outbreak can be traced. Bearing in mind the great lapse of time since foot-and-mouth disease was generally prevalent in Great Britain, it must be the case that a considerable number of veterinary practitioners can have had little or no opportunity to become familiar with the disease in the course of their ordinary practice.

Having regard to the above circumstances, and to the fact that a delay of even a few hours in arriving at a diagnosis may be attended by the most unfortunate results, the Board venture to ask veterinary practitioners who may meet with symptoms in cattle, sheep, or pigs, which in the least suggest the existence of foot-and-mouth disease, to communicate their suspicions not only to the local authority, but also by telegram to the Board direct without avoidable delay, in the meantime taking all possible precautions against the spread of the disease by mediate contagion.

Where this is done the Board will at once instruct one of their Veterinary Officers to confer on the spot with the veterinary practitioner concerned.

ROYAL VETERINARY COLLEGE.

The Session was opened on Monday, October 2nd, at the College, Great College Street, Camden Town, N.W., Mr. W. Hunting occupying the chair. Amongst those present were Col. Duck, Profs. Wooldridge, Woodruff, Shave, and Almound, and Messrs. Banham, Carter, McCormack, Rutherford, and Thatcher.

ADDRESS.

By STEWART STOCKMAN, F.R.C.V.S.

A customary remark from benevolent old gentlemen to small boys is, or at least used to be, "What are you going to be when you are a man?" As I do not wish you to look upon me as a benevolent old gentleman, but rather as one who has gone a certain way along the professional road you are about to traverse, I promise not to treat you as children. Still, gentlemen, if you have not already done so, you must sooner or later ask yourselves what you are going to do when you are qualified, and this brings me to one part of the subject upon which I propose to address you, namely, post-graduate teaching, and post-graduate study. It may seem somewhat curious to address advice to men on post-graduate study before they have finished, and before some of them have even begun,

their under-graduate course. The direction of the latter, however, is provided for by the system of professional education obtaining in this country, which requires students to attend a course of theoretical and practical instruction under teachers at recognised teaching institutions, and afterwards to pass through the ordeal of examination as a test of efficiency, thus compelling them to acquire a certain amount of knowledge before they can pass from one stage to another, and finally qualify. The course of study prescribed for intending graduates in veterinary medicine and surgery is, having regard to its purpose, as wide as that of other professions, but it must be remembered that the amount of knowledge which seems fair to insist upon the average student acquiring in a specified time is necessarily limited: therefore, a syllabus of examination is introduced. A teacher may or may not teach within the limits of this syllabus. He may even think it his duty to do so, but most students are likely to confine their more strenuous efforts within its boundaries, and they can hardly be blamed for this, since it increases their prospects of passing the examinations at the earliest date possible. The restricting influence of this system may be counteracted by prescribing a wider syllabus. That, however, means a longer period of undergraduate study, and as the majority of students, even the most enthusiastic, take up a profession with the object of making a livelihood by supplying a public want, it does not seem advisable that they should be too long debarred from practising their profession, should they desire to do so, nor that the expenses connected with their tuition should be disproportionate to the average income available from it.

Further, although it must be freely admitted that study and teaching up to a certain point expedite the acquisition of skill, which is an indispensable factor in the successful practice of the medical art in all its branches, and that they open up wider fields for its application after it has been acquired, no amount of learning and tuition without practice will make a man skilful in any branch of the medical profession. The minimum time a student should be asked to devote to the study of the multiple rudiments of a profession like medicine has given rise to frequent controversy, which for the present has resulted in the presiding bodies imposing a general curriculum of a comprehensive character, leaving the further pursuit of subjects now universally admitted to require special teaching to those who are able and disposed, to follow them. The universities and colleges have organised post-graduate teaching in connection with some of the subjects, and several medical colleges, exclusively devoted to post-graduate teaching, have recently come into existence.

Certain veterinary colleges in this country have made more or less provision for post-graduate teaching, and it is gratifying to know that the post-graduate course of the Royal Veterinary College, London, has acquired a unique reputation throughout the British Empire. Special degrees and diplomas are granted by the universities and colleges to those who have attended a course of post-graduate teaching, and passed further examinations. The Body presiding over veterinary education in this country, the Royal College of Veterinary Surgeons, has not yet seen its way to grant a post-graduate diploma, conditional to candidates following a special curriculum, and passing further examinations, but it has approved the principle, and has signified willingness to put the latter into practice, when its funds enable it to do so in a manner befitting its public responsibilities. It is to be observed, however, that the scope of these courses of study for post-graduate degrees and diplomas is necessarily limited, that a syllabus of examination is introduced, and that a pass standard is fixed: the students are still in the position of being taught, in *statu pupillari*. Yet, with all its defects the system has much

to recommend it, and it supplies organised teaching of a more advanced kind to formed classes of men who desire to become more proficient in certain subjects. Supplementary diplomas afford evidence of a desire on the part of the holders to obtain more than a bare qualification, the additional learning forms a broader basis for a future superstructure, and they have also a commercial value, something the possession of which professional etiquette allows you to advertise by placing letters after your name, something which at least receives consideration should you apply for a public appointment. I would advise you badly were I to dissuade you from post-graduate degrees and diplomas, but I would like to qualify this advice with a warning not to submit yourselves for too long a period of your lives, or at too mature an age, to those forms of instruction, which bear a resemblance to spoon-feeding. The most desirable kind of post-graduate degree would seem to be one which might be granted to aspirants after a suitable examination, or for original work submitted, in recognition of extensive knowledge and skill in specified subjects, which their powers of self-education have enabled them to acquire by practice and study several years after their days of tuition. But, gentlemen, a man may take many degrees or diplomas by tuition and examination, he may even become very learned, and yet be a comparatively useless person in a profession which is an art founded upon science, and it was not so much to post-graduate study by following a conventional curriculum and taking a diploma that I intended to draw your attention, as to that kind of education a man seek out for himself, and to a certain extent direct.

The position of the veterinary practitioner is the most difficult in this respect. Veterinary clinics and hospitals, where a large and varied number of medical and surgical cases can be seen daily, are only to be found at veterinary schools in very populous cities like London, Paris, Berlin, and Vienna—schools, moreover, which lay themselves out for clinical teaching. Further, the possession of a practice from which he dare not be long absent is an obstacle the practitioner cannot afford to disregard. Still, few men start general practice on their own account for some years after they have received the qualifying diploma, and those who are able to continue their studies will gain more knowledge of clinical medicine and surgery in six months by a well designed course of post-graduate study at one or more of the large veterinary schools, than they will acquire by years spent in general practice. The fees involved are almost negligible, the cost of living as a student in a foreign city is not great, and the expenses of travelling need not be prohibitive. A graduate might attend the clinic and post-mortem room, he might arrange to have the *entrée* to the chemical, physiological, and pathological laboratories, where he can receive direction in relation to the carrying out of chemical and physiological tests applicable to the body fluids and excretions, and be in a position to practise with material from the clinic, the bacteriological and other methods which can be made use of in practice, principally in connection with diagnosis and treatment. He will probably have to make the selection of his own cases, and collect his material, but that is more an advantage than a drawback.

Those who desire to become more proficient in matters relating to State veterinary medicine would be well advised to take out a course of instruction in the ordinary technique practised in pathological and bacteriological laboratories, and to follow this up by spending several months in one or more of these laboratories, assisting the staff, and learning from them by conversation and observation.

In dealing with the suppression of epizootics, prompt and accurate diagnosis is the starting point of every-

thing which leads to success, and an error may lead to the most disastrous results, in some cases even to a national calamity. Further, a veterinary inspector, whether he serves under the central or local authorities, occupies a somewhat unique and very responsible position in relation to diagnosis. Under the Diseases of Animals Act of 1894, the certificate of a veterinary inspector is conclusive evidence in a court of law that disease exists, and practically every Order of the Board of Agriculture lays down that an official diagnosis in respect of all scheduled diseases is to be made by a veterinary surgeon occupying the position of veterinary inspector.

The veterinary surgeon, then, who intends to take up preventive medicine should not only extend his clinical experience of the contagious diseases of animals, but he should devote a good deal of his time in the laboratory to making himself acquainted with the technique and proper application of histological examination, and of those bacteriological methods which are of very considerable value in the diagnosis of bacterial diseases in their occult stages. The behaviour of the test animals of the laboratory towards the viruses of these diseases should also receive much attention. It is not suggested that technique alone will make a man an authority on veterinary sanitary science. It is obvious, of course, that he must also devote much study to the multiplicity of factors which operate in the dissemination of disease, and to methods of control and eradication; that is, to those subjects which have been grouped under the heading of epizootiology. The best fields for educational efforts of this kind are again, the laboratories of the veterinary schools with large clinic and the laboratories of State departments. It is advisable that a portion of the period of study should be spent on the Continent, because a varied experience is of itself educative; and it is necessary, if you wish to make the acquaintance of certain diseases which have been either banished from this country, or not yet allowed to enter it, but for which veterinary inspectors must always be looking out. I refer to such diseases as cattle plague, pleuro-pneumonia, rabies, epizootic lymphangitis, sheep-pox, dourine, and I think even a hypercritical public might agree to foot-and-mouth disease being included in this not unimportant list. It may be asked what length of time a man should devote to this kind of training? I think the reply is, until he feels capable of catching new ideas and methods as they rise, and competent to submit them to examination, that he may not be automatically carried away by every wind that blows, however seductive. It is certain that in this country, at least, the State veterinarian will never have the good fortune of finding a clean slate upon which to commence operations. It is therefore advisable that he should also devote a considerable amount of attention to the relative importance of good science and good administrative government, and to the necessary compromises which must often be made to make his operations accord with both.

Those whose bent decides them to train seriously as scientific investigators will have elected to pursue a course of study which is the most emancipated and attractive, but at the same time the most arduous and endless. Whatever be the subject which has stimulated you to devote yourself to it, training is to be acquired by serving periods of apprenticeship, as it were, under one or several distinguished masters. It is advisable also, that some attention should be given to teaching as a profession, since it is included in the duties of some of the appointments you may wish to obtain.

No doubt you will ask yourselves what the material prospects are for men who have studied hard to acquire special proficiency in the various branches of the veterinary profession. I would suggest to you in the first place that a feeling of greater competence, if it does not

arise merely from conceit, is worth something, and although competence may not always bring material rewards, it very frequently does.

General practice is the widest outlet, and will always absorb the greatest number of followers. Moreover, it is an open-air life, and it is the most lucrative branch of the veterinary profession. Nobody can shut his eyes, of course, to the fact that, in the cities at least, a great deal of horse traction has been replaced by motor driven vehicles. In country practice, however, the horse is by no means the only animal for which the services of veterinary surgeons are required, nor does it seem to be approaching extinction. There has certainly been a falling off in the horse-breeding industry, as regards light horses at least, but, as you are no doubt aware, an organised movement supported by public funds is now on foot to encourage farmers to breed the still very indispensable commodity—the weight-carrying horse.

I am inclined to think that general practice is not nearly so depressed as some practitioners would have us believe, and I would point out that, although the Chancellor of the Exchequer has not seen his way to make concessions in relation to the tax on petrol used by practitioners for their magnificent motor cars, he has so far refrained from threatening the profession with an Insurance Act forcing them to treat their patients for six shillings per head per annum, medicine included.

Those who take up veterinary State medicine must look to the departmental and municipal services for employment. I doubt if it is fully realised that there are at least twelve British Colonies and Protectorates which recruit their veterinary departments exclusively from the colleges of the United Kingdom, while there are several others in which British graduates stand a good chance of employment. Some of the former departments are certainly small, and are never likely to require more than one or two officers, but the majority are considerable, or small only because they have been very recently established. Seven have come into existence in the last six years, five of which promise considerable development. I am in a position to say that at least two important principles influenced the authorities in establishing these departments, namely, that the first thing to do before settling a colony is to settle the question of its animal diseases, as far as possible, and that it would be unwise to send out any but the best qualified men available for this purpose. It is not in the Colonies and Protectorates alone, however, that the expert in State veterinary medicine is in request. At home we have the Veterinary Department of the Board of Agriculture, the chief duties of which are to control and investigate diseases of animals. I hope I may be excused if, for the purpose of accentuating the importance and permanence of organised departments of preventive veterinary medicine, I mention the fact that in the last four years foot-and-mouth disease has in mysterious ways been imported into Great Britain no less than six times, and that each outbreak was completely suppressed in little more than a week at a total cost of a few thousand pounds. This disease was imported five times during the nine months of the present year, and spread to four premises from the original outbreak. The importance of preventive medicine in Great Britain will be realised by consulting the latest returns from the Continent, which show that during August alone 37,737 outbreaks of foot-and-mouth disease were recorded in Germany; in July 12,358 were recorded in Holland; 4,097 in Belgium; and 16,027 in France; where it has been estimated that the loss will amount to over fifteen millions sterling.

In addition to those diseases which are already scheduled, and for dealing with which the services of specially trained veterinary surgeons are required, there

are others of the first importance, notably Johne's disease, epizootic abortion, and tuberculosis. These only await the final ripening process of public opinion to add them to the list. They are not diseases, the prevalence of which is the least likely to be influenced by ordering an extra few hundred cubic feet of air space. Progress will only be effected by reporting, followed by skilful diagnosis, and tracing up the sources of infection with the view of suppressing them, and such work can only be done well by specially trained veterinarians.

I am not going to commit the indiscretion of prediction, but I would observe that the view that the Diseases of Animals Committees of the County Councils should have at their exclusive command the advice and other services of veterinarians specially trained in State Veterinary Medicine, has so much to commend it that it is possibly not very far off consummation.

I have left the largest Department, the Army Veterinary Service, to the last, because in this case special knowledge of preventive medicine is not the sole professional recommendation. I understand, however, that special qualifications of this kind are regarded with no small favour.

In the world of veterinary investigation and research there is ample room for numerous devotees. Veterinary pathology has attracted a few men, but too few to devote their professional lives to its study. Physiological investigation has been almost severely left alone by British veterinarians. The services of veterinary helminthologists are urgently required in the interests of agriculture, and veterinarians with special training and skill in this branch of their profession would be practically sure of employment. Of course it has to be admitted that the prolongation of the period of unremunerative work consequent upon training increases considerably the cost of education. It is difficult to believe, however, that poverty alone, on the part of parents at least, has been the cause of so few graduates training in veterinary science as distinct from practice; but I would like to draw your attention to the material assistance which the Board of Agriculture, from money allocated from the Development Fund, offer to promising graduates who desire to train seriously as investigators. Twelve scholarships of the value of £150 a year for three years will be offered in each of the years 1911, 1912, and 1913. Veterinary graduates of distinction will be eligible for such scholarships; which, it should be noted, will not be awarded to enable the recipient to work for degrees by examination, but to train as investigators. This, however, is not all: under the same scheme for the development of agricultural research and investigation funds will be available to enable certain institutions to maintain workers on specified subjects, some of which are veterinary, and, undoubtedly, there will be a more assured future than heretofore for those whose qualifications deserve recognition. There has never been a time in the history of veterinary medicine in this country, when the prospects seemed so encouraging for those who elect to devote themselves seriously to preventive medicine or to research. I think I might also say that there is no branch of the profession you have chosen which is in the least overcrowded. Small as our numbers are, however, I feel sure that as a profession we will do our best to play up to what new opportunities have been given us, and to make our response a good argument upon which to base demands for more.

To come back now to the all-important question of What are you going to do when you are qualified? May I advise you, while giving the fullest consideration to what men of knowledge and experience have to say, that the process of making up your minds should, in no sense, be a passive one.

The CHAIRMAN in proposing a hearty vote of thanks to the lecturer, said portions of the old question of veterinary education had been discussed in the address, but it had struck him that Mr. Stockman had sounded an original note; and he certainly had shown the value to a student of a post-graduate course, not only in the direction of better mental knowledge, but also in regard to financial reward. Mr. Stockman had pointed out that there were openings abroad and in this country under the State and Municipalities, in all of which the man who had taken the post-graduate course had the better position. He (the Chairman) thought that the lecturer might even have laid more stress on the fact that such a course gave a student a wider basis educationally, with the result that he took double the interest in his work.

Most people, he supposed, had regretted the fact that they had not received as much education as they ought to have done—not at the time; probably they objected to it then, but in the later years that fact came home to them. The majority of men had to take their children away from school at seventeen, and if a boy was away from Polytechnics or other extra educational establishments, he had not sufficient basis for the rest of his education. The lecturer had touched upon that point, and it struck him (the Chairman) as being a very important one. Mr. Stockman also asked the question, How long should a man pursue his post-graduate course? and in reply stated, Just as long as was necessary to make him an exact man, capable of understanding things more thoroughly than he otherwise would. Being an exact man was simply being a scientific man. He asked all present to give a hearty vote of thanks to Mr. Stockman.

The vote was carried with acclamation.

Mr. STOCKMAN, in acknowledging the vote, said it gave him great pleasure to receive the vote. If his few remarks ever came to be of any use, he would be still more pleased.

Principal Sir JOHN M'FADYEAN, in announcing the list of awards, said that on a former occasion similar to the present, he had suggested that before long it might become impossible for the Governors to award the Coleman prizes in accordance with the wishes of the testator. The prizes were at present awarded on the results of special knowledge shown by candidates regarding three subjects:—in the diseases of the horse's eye, diseases of the horse's foot, and glanders. On the occasion when he previously referred to the contingency, he said the time might come when there would be no glanders in this country, and that it would then be, perhaps, unreasonable to expect teachers to be able to train students adequately regarding that disease, or to expect students to have an extensive knowledge of glanders. He was happy to say, speaking now two years later, he could with much greater confidence predict that the time was not very remote when there would be no glanders in this country. That statement did not appear to have received the approbation he had expected. But, although during the past session cases of glanders had not been quite so numerous as in the past, the opportunity would no doubt be continued of teaching students practical connection with glanders during the coming session.

PRIZE LIST.

Coleman Prizes—Silver medal: Mr. J. T. Edwards; Bronze medal: Mr. G. F. Steevenson; Certificate of Merit: Mr. H. E. Hornby.

Centenary Prizes.—Class A: Mr. F. J. Andrews; Class B: Mr. H. W. Dawes; Class C: Mr. R. H. Knowles; Class D: Mr. G. F. Steevenson.

Royal Agricultural Society's Medals.—Silver medal: Mr. J. T. Edwards; Bronze medal: Mr. G. F. Steevenson.

Ralli Prizes in Practical Surgery.—1st Prize, £5 5s. Mr. F. E. Heath; 2nd Prize, £3 3s.: Mr. J. T. Edwards; 3rd Prize, £2 2s.: Mr. W. P. Stokes.

Clinical Prizes.—Class A.—1st Prize: Mr. E. E. Jelbart; 2nd Prize: Mr. W. H. Wortley; 3rd Prize: *æq.* Messrs. F. H. Stanton, C. H. S. Townsend.

Class B.—1st Prize: Mr. H. Hicks; 2nd Prize: *æq.* Messrs. W. H. Priston, R. H. Stalker; 3rd Prize: Mr. W. B. Howe.

Class C.—1st Prize: Mr. E. B. Reynolds; 2nd Prize: Mr. S. J. Gilbert; 3rd Prize: Mr. W. F. Morton.

Class D.—1st Prize: Mr. C. Holland; 2nd Prize: Mr. J. T. Edwards; 3rd Prize: Mr. G. F. Steevenson.

Class Prizes.—Class D.—Veterinary Medicine: 1st Prize: Mr. C. Holland; 2nd Prize: *æq.* Messrs. J. T. Edwards, G. F. Steevenson. Surgery: 1st Prize: Mr. G. F. Steevenson; 2nd Prize: Mr. J. T. Edwards.

Class C.—Pathology: 1st Prize: Mr. S. J. Gilbert; 2nd Prize: Mr. R. H. Knowles. Hygiene: 1st Prize: Mr. R. H. Knowles; 2nd Prize: Mr. S. W. Marriott. Materia Medica: 1st Prize: Mr. R. H. Knowles; 2nd Prize: Mr. W. F. Morton.

Class B.—Anatomy: 1st Prize: Mr. H. W. Dawes; 2nd Prize: Mr. J. M. Penhale. Histology: 1st Prize: Mr. W. B. Howe; 2nd Prize: Mr. H. W. Dawes. Physiology: 1st Prize: Mr. H. W. Dawes; 2nd Prize: Mr. W. B. Howe.

Class A.—Chemistry and Toxicology: Biology: Minor Anatomy: 1st Prizes: Mr. F. J. Andrews; 2nd Prizes: Mr. F. H. Stainton. Practical Chemistry: 1st Prize: Mr. W. H. Wortley; 2nd Prize: Mr. H. H. Curson. Physics: 1st Prize: Mr. R. W. D. Easom; 2nd Prize: Mr. F. J. Andrews.

On the motion of Col. Duck, a hearty vote of thanks was accorded to the Chairman for presiding, and the proceedings terminated.

The Tuberculin Test in Cattle.

In the *Illinois State Register* of August 9th, the views of Dr. James A. Egan, the Secretary of the Illinois State Board of Health, are stated in regard to the use of the test in cows. Dr. Egan commences by conceding that when intelligently and properly applied by a person skilled in its use, and with a working knowledge of diseases of cattle, the test is one of the best means of diagnosing tuberculosis in cows, but he affirms that he is opposed to its indiscriminate application. His chief objections are that it is positive in the presence of the slightest infections which may never spread to the udder, and that it may, on the other hand, be negative and fail to disclose a case of generalised tuberculosis in which tubercle bacilli are being passed in the milk. He is therefore of opinion that dependence on this test may lull authorities and the public into a sense of false security, and he urges the wisdom of examination by competent veterinarians to discover disease, to enforce cleanliness, and to order the segregation of animals clinically tuberculous or with suspicious abnormality of the udders. A large amount of evidence has now accumulated in regard to the uses and limitations of the tuberculin test both in man and animals. It is generally recognised that the test may be negative in milinary tuberculosis, in advanced cases, and in tuberculous meningitis, and that it may be positive in quiescent or clinically inactive lesions. It is, moreover, obviously inapplicable when there is fever. In spite of these limitations it is a useful test, and, according to Mohler in a Bulletin presented to the Public Health and Marine Hospital Service of the United States in 1908, it affords accurate diagnosis in 97 per cent. of cases in cattle. We agree with Dr. Egan that it would be unwise to rely

upon this test only and we endorse his plea for intelligent and skilled examination of the cows as well, but if the test were carried out by competent veterinarians this would be ensured. We do not agree that the physical examination should alone be relied on to the exclusion of the tuberculin test or that only clinically tuberculous cows should be excluded. The ultimate object of hygienic measures in regard to the milk supply is the eradication of the disease, and it is generally admitted that this is not easy to recognise in cattle in the early stages by physical examination only. It is also important to note that the experiments of the Royal Commission on Human and Animal Tuberculosis proved that bacilli may be present in the milk of cows with tuberculosis but showing no evidence of disease of the udders.—*The Lancet*.

Flies and Infection.

A fourth report on flies as carriers of infection issued recently by the Local Government Board contains a continuation of Dr. Graham-Smith's experimental work on the relation of flies to bacteria, an investigation of their relation to parasitic worms by Dr. Nicoll, and a series of observations on the flight of flies by Dr. Copeman and others.

Dr. Nicoll's report deals with the transmission of the eggs of parasitic worms through the agency of house-flies. The only investigations recorded of any importance were made in Italy nearly thirty years ago by Grassi, and twenty-three years later by Grassi, and twenty-three years later by Calandruccio. Their observations left little doubt that the fly was an extremely probable agent in the dispersal of certain worms—notably *Hymenolepis nana* and *Trichocephalus dispar*. They also showed that the eggs were carried in the intestine of the fly and deposited in its excrement. Dr. Nicoll's work yields ample confirmation of these conclusions, and brings out several new points. Both he and Graham-Smith remark upon the fly's habit of cleansing itself. This apparently hygienic procedure might at first commend itself, but, although it serves to get rid of gross contamination, it results in a renewed infection of the legs and body from the proboscis. Nicoll sums up the general facts which are known in regard to the life-history and mode of transmission of parasitic worms and the characters of their eggs. The size of the latter appears to be the most important factor in their relation to flies, for the ordinary house-fly is unable to swallow particles exceeding 50 μ in diameter. This fixes a limit to the size of egg which can be ingested, and, as many parasites produce eggs exceeding this size in one or both diameters, they must be much less likely to be disseminated by flies. The experiments were conducted chiefly with the tapeworms, *Hymenolepis diminuta* and *Tenia serrata*. The former produces eggs exceeding the limit; the latter much under. It was found that the eggs of *Tenia serrata* could be ingested in hundreds, that they might remain in the intestine of the fly for two or three days without being destroyed, and that, when deposited, they retained their infectivity. It was further noted that faeces containing tapeworm segments afforded flies the opportunity for contaminating food for at least a fortnight after exposure. With regard to the conveyance of eggs on the external surface of flies, although this was demonstrated several times even in the case of such large eggs as those of *Hymenolepis diminuta*, Nicoll is evidently not inclined to attach such far-reaching importance to this mode of transmission as to that by the intestine, and in this respect he is in agreement with Graham-Smith in the case of bacteria. It is obvious that, where foodstuffs and infective excremental matter are separated by no great distance, external conveyance is the most ready means of transmission.—*B. M. J.*

J. KNOWLES, V.S., Murrow, Wisbech, Cambs., died on
Sept. 27, from cerebral apoplexy. Aged 73 years.

CORRESPONDENCE.

UNUSUAL SKIN AFFECTION IN CATTLE.

Sir,
I was much interested in the cases of skin affection described by Mr. Hills in *The Veterinary Record* of September 30th. Evidently the outbreak is similar in many respects to the disease that exists in the South of Ireland. As I am now treating a typical case in a milch cow close to town I have a better opportunity of observing the course of the disease than on other occasions. This animal shows in addition to the lesions at the back of the knees, an eruption over the neck and shoulders. This eruption is in the form of small, hard papules which have a "shotty" feel, these develop into pustules, and after a time "scab" over, and a smooth surface is left when the scab falls off or is removed. The lesions at the back of the knees were very severe, the skin sloughed off in a large patch, and an extensive unhealthy surface resulted, with little tendency to heal. Small ulcerated patches also occurred at the posterior aspect of the metacarpal region.

The owner informed me that the first appearance of the disease observed was at the back of the knees, in the form of similar pustules to those now present on the neck and shoulders.

I may mention that ointments or liniments of any kind seem to aggravate the condition, an application of oxide of zinc and boric acid gives the best results. I need scarcely point out the difficulty in treating a large number of young cattle, as the procedure of catching them is by no means easy, nor is it relished by the owners.

The disease is now prevalent in various districts, and unless the animals are cured before cold, wet weather sets in it is likely that complications will arise, and considerable loss will result. Cattle suffering from the affection will not be purchased at either fairs or markets, once the public get to know its contagious nature.—Yours etc.,

E. WALLIS HOARE.

Sir,

I was very interested to read in *The Veterinary Record* of Sept. 23rd Mr. Wallis Hoare's article on "An unusual skin affection in cattle," as I have met with several such cases this summer.

The animals chiefly affected have been dairy cows, the majority of which were Jerseys, but at one farm several Devon bullocks were affected, at another several Jersey calves, and these at first gave one the impression they were suffering from ringworm; at another farm a Dutch bull was affected in both hind legs.

The symptoms described by Mr. Wallis Hoare are like those I met with, and nearly always the back of knees was the first place noticed, but soon the skin between the knee and the fetlock was affected causing great irritation and

swelling of the legs; the animal walked very stiffly, and when lying, did so with its legs extended. The Dutch bull had both hind legs affected nearly up to the stifles. The calves were affected on the legs, but there were also various circular patches over the the body denuded of hair, just like ringworm, in fact I was called in to attend them for this; the patch differed from ringworm in that the patch of dead hair and skin could be pulled clean off. I do not consider it is contagious, and I believe the whole trouble is caused by flies. Eczema breaks out at the back of the knees, and is increased by the cows constantly licking the parts—scores of flies continue to settle on the sores and so make matters worse. The back of the knees seems to be a favourite spot for flies, and I must confess that I have never before seen the animals tormented by flies so much as I have this year.

The treatment I adopted was first to prevent the animal licking the sores, and to keep the flies away; this I did by putting on a cradle and in bad cases putting the animal into "trousers"; in ordinary cases the cow's legs had to be syringed with a disinfectant solution before they would stand still to be milked. An aperient if necessary, and an astringent, antiseptic ointment applied twice a day seemed to be sufficient, and in about three weeks they were right again. The cows were kept in during the day and turned out at night.

I have seldom before met with similar cases and certainly have not had them so bad nor had so many affected as during this exceptional summer. It would be interesting to hear the experience of others.—Yours faithfully,

WALTER W. GOLDING, M.R.C.V.S.

Hertford, Oct. 4.

Sir,

During the last fortnight I also have had a similar case of skin affection in cattle, as described by Mr. Wallis Hoare in *The Veterinary Record* of Sept. 23rd.

Four steers were affected in a herd of eighteen; they were two years old and showed precisely the same symptoms: swollen knees and arms, with an angry, painful scaling of the skin from the back of the knees down to the fetlock joints. When made to move they walked very sore upon their toes, and when recumbent they showed great disinclination to rise. Eventually a deal of sloughing took place. They were turned out in a field through which a stream runs, and I put the cause down to their standing so much in the water this season.

I found that an aperient, with emollient liniment: afterwards an healing dressing to the sloughs has been sufficient to effect a cure.—Yours truly,

FREDK. AIREY, M.R.C.V.S.

Biggleswade, Beds. Oct. 4.

DISEASE IN PIGS—ANOTHER ENQUIRY.

Sir,

I notice an enquiry in *The Record* for Sept. 30th ult. as to a disease of young pigs, the symptoms of which were simply those of extreme peeling of the skin, and which in every instance ended fatally. This note is not intended as an answer, but simply as a supplemental enquiry.

A short while ago, I visited two litters of very young pigs which appeared to be affected with a similar disease. They all showed extreme erythema and peeling of the skin and, in addition, the usual signs of fever: thirst, etc., but no marked diarrhoea or other symptoms. On making a post-mortem examination of one of them, I discovered no unusual lesions. The stomach contents were more or less normal, and the bowel contents were of the nature of soft putty, and somewhat slate-coloured, but there were no signs of gastritis or enteritis—ulcerative or otherwise.

I may remark that the sows had been partly fed on boiled fish offal, but I am not aware that this, through the medium of the milk, should make any difference to the health of young pigs. Moreover, both the sows appeared to be quite well, though all the youngsters died.—Yours truly,

M.R.C.V.S.

BLACKLEG

(QUARTER-EVIL. SYMPTOMATIC ANTHRAX.)

The New Zealand Official Report on Blackleg shows that the mortality from this disease has been reduced by 75 per cent. since vaccination was made compulsory. The vaccine is supplied in convenient form under the name of

"BLACKLEGIDS."

"Blacklegoids" are easily administered by means of the "Blacklegoid" Injector.

Extract from a letter which appeared in *The Veterinary Record*, January 25, 1908: "About five years ago I commenced to inoculate with Parke, Davis & Co.'s 'Blacklegoids,' and since then I have lost only one, and that was this year, out of over 900 inoculated since I commenced. I may mention that I have no interest in Parke, Davis and Co.'s preparations."

Co. Kilkenny, December 28th. 1907.

The Stock Inspector of the Pastures Protection Board, Singleton, Australia, when ordering (May 17, 1907) 200 doses of "Blacklegoids," stated: "This is the third year I have used your 'Blacklegoids,' with a result far better than I or the owners of the cattle ever anticipated. I do not know of an instance where it did not act as an immediate preventive."

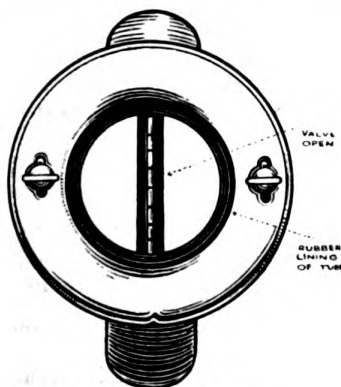

Further particulars will be sent on request by

Practices for Disposal

GOOD-CLASS General Practice in first-class sporting district in the South Midlands, represented as returning between £450 and £500 p.a. is for disposal under satisfactory reasons. Further particulars in confidence will be given on application.

OLD established practice is for immediate sale, vendor having obtained an appointment. Situate in the Eastern Counties. Good agricultural district. Returns represented as being £450 p.a. C.C. inspectorship. Excellent house and stabling. Two acres of grass paddock. Price, in order to secure quick sale, £300, to include drugs, fittings, instruments, trap and cob.

AN exceptional investment for a smart man desirous of South African Practice. An opportunity of securing a partnership in an excellent equine and canine practice, established for 18 years. Represented as returning on average for last three years over £1000 p.a. Letter just to hand states: returns for first 6 months this year have been £607 10s., and that this is capable of great increase. Capital required (to include half-share of practice and valuation of surgery) under £600. References exchanged. Further information will be given to bona-fide applicants.

Wanted

PARTNERSHIP, with view to succession, in a good-class sporting practice, desired by an experienced M.R.C.V.S. with capital at command. Good horseman. Particulars will be received in strictest confidence.

THE 'RECORD' PRECISION SYRINGE.

The FINALITY of
Hypodermic and Serum Syringes.

"The **"Record"** Precision Syringe is a piece of delicate mechanical workmanship well deserving its name. It meets **all requirements as regards aseptic conditions and accuracy and it is always ready for use.**

It consists of **metal and glass** only. The glass barrel is ground inside perfectly true to cylindric form. The Nickel vacuum piston is "ground in" into the glass barrel by precision machinery so as to fit hermetically, it slides smoothly, yet tightly, **without any lubricant.**

The cover is fixed on the cylinder with a **bayonet-fastening**; for the purpose of **thorough cleaning** it is provided with a segmental incision, by means of which it can be detached from the piston-rod by sliding it off side-ways. When **completely** taken apart the Record Syringe **forms 3 parts only: cover, piston and barrel.**

The **Needles** are provided with the original "Progressive" **flat** mounts. By this arrangement a good hold is afforded to the operator.

The fixing of the needle itself in the mount, by means of a smooth longitudinal guide arranged above the screw threads prevents the needle from breaking off in the mount.

EVERY SYRINGE IS GRADUATED BOTH IN C.C. AND MINIMS.

Price with 2 Steel Needles in Metal Case—20c.c. 21/- 10c.c. 17/6. 5c.c. 15/- 2c.c. 10/- 1c.c. 9/-

PRACTICES FOR DISPOSAL

WEST OF ENGLAND. Town practice held nearly 20 years by present incumbent. Receipts: 1910 £1172. Contracts produce £251. Good house containing 5 bedrooms, 3 recept. etc. garden, stabling. Working expenses light. Premium £1500.

LONDON, W. Good-class practice returning about £600 per annum, with forge the gross returns from which are stated to be about £1000 per annum. Working expenses are exceptionally low. Convenient, well-situated house, rent £70 inclusive. Forge rent £69. Contracts produce about £300 per annum and could be greatly increased by practitioner willing to accept lower fees. Premium £1000.

WEST OF ENGLAND. Practice in good breech and hunting district, returning £600 per annum. In present hands 10 years. Convenient house with surgery, stabling etc., rent £55. Premium one years purchase.

SOUTH COAST. Country practice returning about £835 per annum, including appointments producing about £70. In present hands 24 years. The practice has been worked by an assistant who would remain if desired. Convenient house, rent £21, larger available if required. Premium £800.

IRELAND. Partner wanted to take charge of practice returning about £1200 per annum. Rent of premises £82 per annum inclusive. Contracts produce over £400 per annum. Practice has been in present hands 12 years. Premium required for half-share £500.

HEALTH RESORT. Practice returning £650 per annum, chiefly dog. Good house with large yard, stabling, kennels, etc., rent £85, or would sell freehold. Premium £750. Valuation optional.

LONDON, N. Very old-established practice returning about £1200 per annum. Good house and thoroughly convenient premises, rent £90. The practice is principally horse. Receipts are increasing. Premium one years purchase. This practice is well-known to us and can be recommended.

LONDON, S. Practice producing over £1000 per annum. In present hands nearly 40 years. Good house, with stables, kennels, etc. rent £70. The practice is principally dog with some horses and dairies. Vendor retiring. Premium one years purchase.

SURREY. Rapidly increasing, well-established practice returning about £1000 per annum. Small house with stabling, kennels, etc. Capital required, including valuation, will be about £1300. The practice is well-known to us and can be thoroughly recommended to a suitable man.

HIGH-CLASS mixed practice returning about £650 per annum. Good premises would be let on lease or sold if preferred. Premium £600.

SEASIDE, SOUTH COAST. Partner wanted in practice returning nearly £700 per annum, and capable of great increase. Incoming partner must be good allround man. Premium for half share £300.

Each line above five—first insertion 6d; after first 3d.
Average—seven words in a line.

These Advertisements will not be inserted unless prepaid, and if replies are to be received at this office an extra sixpence must be included.

Lincolnshire V.M.A.

A MEETING will be held at the "Albion" Hotel, Lincoln, on Friday, October 20th. Professor F. Hobday will give a demonstration upon Dr. William's "Operation for Roaring," at the yard of Messrs. Hartley and Son, at Friar's Lane at two o'clock. Mr. W. W. Grasby, M.R.C.V.S., of Daventry, President, will take the chair at the meeting, at 3 o'clock. Agenda Routine business. Address by Professor F. Hobday upon the Ventricle Operation. Members are invited to exhibit Pathological Specimens. Tea at 5 o'clock.

C. W. TOWNSEND, Hon. Sec. & Treas.

West of Scotland V.M.A.

A Meeting will be held within the Religious Institution Rooms, 200 Buchanan Street, Glasgow, on Friday, 20th inst. at 4.30 p.m. A paper will be read by Mr. James McFarlane, M.R.C.V.S., on "Horses Suitable for Heavy City Work." ROBERT MITCHELL, Junr., Hon. Sec. & Treas.

To Veterinary Surgeons

YOUNG unmarried veterinary surgeon required for British Colony, must be fully qualified and have taken course of tropical bacteriology, £400 to £450, with free quarters and passage. Write, stating record and enclosing copies of testimonials, E. F., c/o J. W. Vickers & Co. Ltd., 5 Nicholas Lane, E.C.

As Assistant

M.R.C.V.S., (1899) wants post as assistant, steady. References furnished on application. Address, 2101 V.R., 20 Fulham Road, London, S.W.

Wanted

DECENT veterinary surgeon to take over a sound practice, returning £420 and increasing yearly, principal wishing to retire. Very moderate price, easy payments and a good introduction given. Address, 2102 V.R., 20 Fulham Road, London, S.W.

Assistant Unqualified

SON of V.S. aged 26, seeks situation, experienced mixed town and country practice, well up in all branches. Energetic, good dispenser and book-keeper. Ride, drive and cycle, not afraid of work. Present situation 18 months, excellent references. Dis-engaged October 28th. W. Andrews, c/o Wartnaby & Sadler, 89 Horninglow Road, Burton-on-Trent.

For Sale

PRACTICE in best breeding district in Cumberland. Been in family nearly fifty years. No opposition. Good introduction given. Full particulars on application. Address, 1101 V.R., 20 Fulham Road, London, S.W.

Mallein and Tuberculin

MEMBERS of the Profession may obtain Mallein and Tuberculin on application to the Principal, Royal Veterinary College, Camden Town N.W., on the following terms: in bottles, 6d. per dose. Minimum quantity supplied, two doses. In hermetically sealed tubes, containing one dose each (specially suitable for use abroad) 1s. per dose.

G. H. PICKWELL, M.R.C.V.S.

Locum:

(Gone to India till early 1912).

73 Victoria Mansions,
South Lambeth Road, S.W.

HUGH R. SINGLETON, M.R.C.V.S.

Locum Tenens.

Disengaged September 23rd,

44 St. Michaels Road,
Bedford.

Locum Tenens

L. A. F. DAWSON, M.R.C.V.S.,

Disengaged October 14th.

Address:

Belton, Uppingham.

Telephone: No. 2, Belton.

Locum Tenens

MR. WALTER G. GREEN, M.R.C.V.S.

"Rosenheim,"

Boscombe Park,
Bournemouth.

To Veterinary Surgeons

M.R.C.V.S., qualified 1906, good experience of all branches of the profession, requires position as partner or manager, with view to early succession. Address, 1105 V.R., 20 Fulham Road, London, S.W.

For Disposal

GENUINE, old established town and country practice doing nearly £600 a year. No forge. Worked with small car. Three months introduction. Present practitioner retiring. Price, with good stock of drugs £325. Surgery fittings, instruments etc. may be taken at valuation. Address, 5110 V.R., 20 Fulham Road, S.W.

As Assistant

GERMAN Veterinary Surgeon with best references wants a situation as assistant until he masters the language, au pair or on small terms. Reply under I.A. 6644 to Rudolph Mosse, Berlin S.W. 19.

As Assistant

BY M.R.C.V.S., (1909), aged 25, assistantship in large mixed practice. Practical, sober, industrious. Excellent testimonials. Address, 1102 V.R., 20 Fulham Road, London, S.W.

All communications respecting advertisements should be addressed to

H. & W. BROWN, 20 Fulham Road, London, S.W.

Tracheotomy Tubes

MISS JONES, successor to F. B. Jones, M.R.C.V.S., still continues to supply the Special Tracheotomy Tubes patented by her late father. Special terms to Veterinary Surgeons. Address, 86 Kimberley Road, Leicester.

Victoria Veterinary Benevolent Fund

President—E. COLEMAN, Esq., Tooting Graveney.

FUNDS are urgently needed to enable the Society to extend its relief to distressed Members of the Profession, or to widows and orphans of deceased veterinary surgeons. Annual subscriptions, or donations will be gratefully acknowledged by the Hon. Sec. and Treas.

W. F. BARRETT, Fountain Court, Temple, E.C.

To Veterinary Surgeons

ADVERTISER, ex-student with extensive experience, well up in all branches, wishes to join veterinary surgeon in or near London and assist him in his practice. Single: live in or out: terms moderate. Address, 1104 V.R., 20 Fulham Road, London, S.W.

To Veterinary Surgeons

LOCUM, assistant, branch manager, veterinary surgeon desires permanency, sporting, hunting, country practice. Experienced, reliable, practical, hard worker, castrate standing, good obstetrician, 34, single. Excellent references, interview. Address, 5074 V.R. 20 Fulham Road, London, S.W.

Wanted

M.R.C.V.S. practical and experienced requires engagement as manager. Locum or assistant. Good references. Address, 6110 V.R., 20 Fulham Road, London, S.W.

AGENTS REQUIRED in unrepresented districts for the IMPERIAL ACCIDENT INSURANCE Co., LD. Est., 1878. Horses Insured against Death from Accident or Disease, Mares for Foaling and Loss of Foals; Farmers' Liability for Accidents to Labourers, Servants, and Workmen's Compensation. Claims paid, £500,000. Address Agency Manager, 17, Pall Mall East, London, S.W.

Partner Wanted

IN old established horse and dog practice, on the South Coast, average returns £650. Price for half-share £300. Easy terms may be arranged. Address, 1509 V.R. 20 Fulham Road, London, S.W.

For Immediate Disposal

WORKS, North Riding. Wanted, reasonable offer. Receipts over £300, good house to go with practice. Rent £12. Good agricultural and breeding district. Present owner 27 years; no opposition; C.C. appointment: introduction given. Address, 5092 V.R., 20 Fulham Road, London, S.W.

Situation Wanted

RESPECTABLE young man with experience of dispensing, veterinary work and book-keeping, requires position. Terms moderate, total abstainer. Address, 5095 V.R., 20 Fulham Road, London, S.W.

Notice

WILL gentlemen wishing to advertise in this column please note that our time for receiving is Thursday MORNING, and that 2 p.m. is "Latest."

The Journal of The Board of Agriculture

ISSUED on the 15th of each month. Twelve month 4/-, three months 1/-, or single copies 4d., direct from the Board of Agriculture and Fisheries, 4 Whitehall Place, London, S.W., or through any bookseller.

Change of Address

W. T. BROOKES, M.R.C.V.S.,

Veterinary Infirmary and Shoeing Forge,

The Butts, Warwick.

Late 20 Jury Street, Warwick.

For Disposal

WARWICK, freehold house, 20 Jury Street. Veterinary surgeon's business carried on upon premises for over 50 years, in main street, country town, good hunting district. 3 reception, 6 bedrooms, bath, large yard in rear. 5 loose boxes, stall, large shoeing forge, saddle room, loft, surgery. Possession to day. Ledbrook, Solicitor, Warwick.

As Manager, Assistant or Locum

QUALIFIED veterinary surgeon, experienced both town and country, wishes post as locum, manager or assistant, indoor or out. First-class references. Address, 5097 V.R., 20 Fulham Rd., London, S.W.

For Disposal

SNUG practice in fashionable resort in the West, returning £200, capable of being doubled by canine practitioner. Will sell at low figure. No opposition. Address, 4087 V.R., 20 Fulham Road, London, S.W.

Locum Tenens

M.R.C.V.S., thoroughly used to country practice and holding testimonials as to ability and general character from many practitioners, is always open to engagement when not actually filling a post. Permanent Address, "Locum," 59 Gascony Avenue, London, N.W.

Chlorodyne

FOR SALE, a large quantity of Chlorodyne, full strength, B. P. 1885, at 2/- per pound. H. J. Pratt, Wholesale Druggist, Cleckheaton.

Missing Numbers

OWING to claims for missing numbers reaching us often many weeks after date of issue, we have to notify that claims for non-delivery will not be accepted if the date of origin is later than four weeks from date of due delivery in the case of foreign subscribers, or more than fourteen days after printed date in the case of inland subscribers.

Principal and Dean : Professor SIR JOHN M'FADYEAN, M.R.C.V.S., M.B., B.Sc.

Membership Diploma of the Royal College of Veterinary Surgeons :

Complete Courses of Instruction are conducted in all the Subjects of the Examinations for this Diploma. The facilities, etc., afforded for the Practical Training of Students are unrivalled.

Bachelor of Science Degree, University of London.

The Professors of Chemistry, Biology, Anatomy, Physiology, Hygiene, and Pathology, are Recognised Teachers of the University, and conduct in their respective subjects courses which qualify for the Science Degree (B.Sc.), which may be taken concurrently with the above Diploma.

POST GRADUATE COURSES.

These Courses in Veterinary Pathology and Bacteriology are conducted under the supervision of the Principal and are specially adapted to the requirements of officers of the Army Veterinary Department, Colonial Veterinary Surgeons, Veterinary Inspectors under the Contagious Diseases of Animals Acts, and Candidates for the Fellowship Diploma of the Royal College of Veterinary Surgeons.

The number of places for these Courses is limited and early application must therefore be made to prevent disappointment. The next Course will begin on Monday, October 7th, and terminate on Friday, November 29th, 1912.

The College Calendar, containing full particulars, will be forwarded on application to

The Secretary,

Royal Veterinary College, Camden Town, N.W.

THE VETERINARY RECORD

A Weekly Journal for the Profession.

EDITED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1214.

OCTOBER 14, 1911.

VOL. XXIV.

THE DANGER OF RABIES FROM FOXES.

A fortnight ago we reprinted a newspaper report of an inquest upon a Master of Foxhounds, at which the medical opinion was expressed that death was due to hydrophobia. There was a clear history of a bite from a hunted fox, received near the end of last hunting season, and the symptoms of the subsequent fatal illness in September, as reported, certainly read very like those of hydrophobia. Nevertheless, veterinary surgeons and medical men alike would generally regard the diagnosis as open to grave doubt. No case of animal rabies has been established in England since 1902, and it is difficult to believe that the disease can have lingered so long amongst foxes without being transmitted to dogs. Again, it is known that there are acute nervous affections of the human subject—though it is true that such cases are rare—the symptoms of which may closely simulate those of hydrophobia. Taking the report as it stands, it certainly cannot be held to prove the existence of rabies in England.

Facts have since transpired, however, which tend to support the diagnosis of hydrophobia. We hear that a number of foxes have been imported into England, and that some of these were certainly set free in the district in which this alleged case of hydrophobia occurred. This fact puts a different complexion upon the matter. It does not, of course, prove that the diagnosis in this one case was correct. But it opens the door to the possibility of a recent importation of infection amongst foxes in the district in question—along with other districts, and thus considerably weakens the previous grounds for doubting the diagnosis. Upon the whole the probability seems to be that the case was one of hydrophobia.

This reveals a loophole in our existing regulations against rabies. The importation of foxes should certainly be stopped, and we hear that steps are already being taken in this direction. Doubtless, also, some enquiry will be made as to whether the importation of other species of animals, which has hitherto been unchecked and almost unnoticed, may not constitute a possible source of danger. It is clear that for some time to come, veterinary surgeons should remember that local outbreaks of rabies, especially in the country, are at least possible, and they should keep upon the alert. It goes without saying that the district in which this case occurred, and especially its pack of hounds, will be carefully watched.

VETERINARY SCIENCE AND ITS RELATION TO THE COMMUNITY.*

By Dr. O. CHARNOCK BRADLEY.

The name and memory of William Dick, a native of this city, born in White Horse Close, will ever be held in reverence by the profession of which he formed so distinguished an ornament. To his penetrating foresight and indefatigable energy the genesis of this College is due. On his loyal and great-hearted generosity the continuance of the College after his death depended. Eighty-eight years ago Dick might have devoted his energies to the conduct of a private practice and the accumulation of wealth. Fortunately for veterinary science his was a more altruistic character. Instead of working for his own gain merely, he followed the advice of Dr. John Barclay and, in a humble way, laid the foundation of the first veterinary school in Scotland. Of what the germ of his school was like we can form some idea from the words of one who wrote as an eye-witness. "You may fancy to yourself," says the writer, "a room of no very great dimensions in an old and apparently long untenanted house in Clyde Street. You enter it from the street door and are immediately struck with the delightful confusion which seems to reign within. Skeletons of all descriptions, from a horse to an ape, not ranged in regular order "all of a row," but standing higgledy-piggledy, their ranks having been broken by the Professor's table, and their heads looking in all directions, as if thrown together by chance. . . . Of that portion of the house which is set apart for the audience, the best thing I can say is that whenever I dropped in I have always found it remarkably well filled. It is fitted up with rough deal plauks, set upon rough props; the seats rising tier above tier until your head touches a very dark-coloured ceiling."

From this modest beginning the College grew, and grew rapidly. Extension after extension was made; elaboration after elaboration became necessary. In the beginning Dick was unassisted; but ultimately he was forced to gather around him a staff of teachers, some of whom later became famous in the veterinary and wider scientific world.

I think that without the slightest exaggeration or distortion of facts we may say that as Dick's College grew, so came into being a veterinary profession in Scotland, and the growth of the two was interdependent. When the veterinary school was first projected a veterinary profession could scarcely be said to exist on this side of the Border. We are told that at that time there were not more than a dozen practitioners in Scotland, with the result that animal owners were almost entirely at the mercy of charlatans and quacks of the most ignorant description. With the dissemination of veterinary knowledge resulting from the establishment of the Clyde Street School properly qualified practitioners became increasingly numerous and of vastly improved training.

* Inaugural Address delivered at the opening of the 89th Session of the Royal (Dick) Veterinary College, Edinburgh, October 4, 1911.

The rule-of-thumb man gradually—unquestionably, very gradually—gave place to him who was equipped to take a more scientific and therefore more commonsense view of the causes and treatment of animal diseases.

When William Dick died in 1866, "in the full tide of successful experiment," he had stamped upon veterinary science so indelible an impression that the good work he had initiated continued, and became ever more and more fruitful.

Veterinary science, not only in Scotland, but in the United Kingdom and throughout the whole civilised world, has benefited by the movement which had its origin in the "old and apparently long untenanted house in Clyde Street." It was said during Dick's lifetime, and has been said since his death, that the Clyde Street School catered for the requirements of Scotland only. This is not, and never has been, according to fact. While Dick was still living 818 students graduated from this College, and of these barely more than half belonged to Scotland. A large proportion came from England and Wales, some from Ireland, and others from the Colonies and from foreign countries. Clearly the Edinburgh Veterinary College in those days was not parochial. What was true from 1823 to 1866 remains true to-day. Into the uttermost parts of the earth, beyond the confines of the seven seas, men have gone forth from the narrow and somewhat gloomy street where for all but ninety years the school has been located. Not long ago it was possible to say that the Principals of all the Veterinary Colleges in the United Kingdom could claim the Clyde Street School as their *alma mater*, as can at the present moment the heads of the schools in London, Glasgow, Dublin, Sydney. Not only in Scotland are graduates of this College practising their profession, but an examination of the official Register of Veterinary Surgeons shows that practitioners trained within these walls are doing their work and maintaining the traditions of the school in every county of England, in every county but one in Wales, and in every county but three in Ireland. They are to be found in nearly all the King's Dominions beyond the seas. They may be met in many of the States of North America, and in South America.

To give a list of famous men who have sat on the benches within this College would be tedious from its length. Let it suffice to say that former students have occupied and are occupying the most exalted positions in their profession. Almost as tedious would it be to recount the names of famous men who have been teachers in this school. Taking merely a few who have attained world-wide repute, and avoiding the perils attendant upon an assessment of their eminence, the roll contains the names of Sir James Dewar, Fullerian Professor of Chemistry, Royal Institution; Sir John M'Fadyean, Principal of the Royal Veterinary College, London; James McCall, Principal of the Veterinary College, Glasgow; A. E. Mettam, Principal of the Royal Veterinary College of Ireland; Stewart Stockman, Head of the Veterinary Department of the Board of Agriculture and Fisheries; Daniel John Cunningham, the much lamented late Professor of Anatomy in the University of Edinburgh; J. G. McKendrick, Emeritus Professor of Physiology in the University of Glasgow; Isaac Bayley Balfour, Professor of Botany, University of Edinburgh; James Arthur Thomson, Professor of Natural History in the University of Aberdeen. These, as well as other men of eminence, have helped to make the school what it is, and have influenced, and been influenced by, the traditions of the institution.

Were we asked to state adequately but briefly what veterinary science has done since the time William Dick first entered Clyde Street as a teacher, we should find the task one of great difficulty, and of difficulty because of a richness of material. Beyond question veterinary science has performed a humanitarian function of sur-

passing moment in that it has rescued animals from the rough and ready, and even barbarous treatment to which they, when ailing, were subjected during the earlier part—nay, even during a later part—of the nineteenth century. An examination of the tattered manuscript books which it was, and possibly still is the custom to hand down from father to son among farmers, village smiths, and country quacks, produces a feeling of wonder that animals could survive the treatment to which they were subjected, and the weird and loathsome decoctions with which they were drenched. Unquestionably the growth and development of veterinary science has resulted in more humane and therefore more efficacious modes of treatment.

Descending from the humanitarian to the utilitarian standpoint, it can be claimed without hesitation that veterinary science has been of inestimable benefit to the community. In how far the wealth of the country has been, and is being conserved cannot be definitely computed, but an approximation may be attained by the examination of published statistical tables showing the prevalence of contagious diseases and the loss of animal life arising therefrom during the past thirty or forty years.

The recent outbreaks of foot-and-mouth disease have caused a certain amount of commotion among stock-keepers, and trade has been in a degree affected. What must have been the result of the 18,732 outbreaks in 1883 when no fewer than 461,145 animals of various kinds were attacked! And what the dislocation of trade when in February of that year all the country markets were closed for a month.

Contrast the isolated and, now-a-days, infrequent appearances of the disease in the United Kingdom with the returns as given for Continental countries. On the 15th June in Germany alone there were no fewer than 16,504 infected places. Holland had 4,602 outbreaks during the month of May. In Italy 25,004 animals were affected during the week ending April 30th; and in Russia there were 58,274 cases in the month of February. By contrast the returns made by our own Board of Agriculture pale into almost absolute insignificance. Nevertheless it cannot be forgotten that a severe outbreak of foot-and-mouth disease would be a very serious thing. Recently Sir Edward Strachey has, in public utterance, pointed out that not only would there be great loss to the agriculturist, the general public would suffer enormously because of a shortage of milk. This possibility makes it incumbent upon the State to encourage, if not to institute, detailed investigation of the mode of transmission of, and possibility of complete protection from the disease.

The annual reports of the Board of Agriculture afford abundant evidence of the saving of animal life from other contagious diseases, and the consequent prevention of monetary loss to the country.

Cattle plague, which on more occasions than one has produced the wholesale decimation of herds, has been unknown since 1877. In 1891, 9,491 cattle were slaughtered on account of 192 outbreaks of pleuro-pneumonia. This disease has not been known in this country since 1898, whereas from 1891 to 1898 inclusive nearly 16,000 animals were destroyed.

Thanks to efficient steps having been taken, rabies (the very name brings terror) has ceased to exist in this country.

Sheep-scab, which formerly caused so much loss to sheep-owners, is steadily declining, so that last year there were only 556 outbreaks as compared with 1,939 eleven years ago, and 3,092 sixteen years ago.

Glanders, a disease to be feared by man because of its capacity of transmission from animals to the human subject, has also shown a steady decrease during recent years.

The only serious animal diseases which have not as

yet been materially affected by preventive measures are anthrax and swine-fever. These have offered problems difficult of solution, but there is no reason to despair of the ultimate reading of the riddle. Other diseases have prevailed for a time, but scientific investigation and the application of knowledge arising therefrom have ultimately resulted in their subjection. There is much to be hoped for in inoculation and serum-therapy.

While speaking of contagious diseases, it is perhaps not entirely beside the point to make reference to certain facts relative to diseases among animals in more distant parts of the Empire. As will be readily admitted, the presence of contagious animal disease is a factor which tells heavily against the spread of civilisation and the development of the resources of our colonies. Clearly, man cannot establish himself permanently and satisfactorily in any part of the world without domestic animals. Man situated in those regions where animals survive with difficulty is, therefore, seriously handicapped. This is the case in certain parts of Africa. I have been informed recently that during 13 months some 44,000 cattle have died in one single district from East Coast fever. Translate these figures into pounds, shillings, and pence and we appreciate something of the troubles of the African stock-keeper. It is scarcely necessary to say that the authorities are quite alive to the fact that this state of things, and the proper development of the country are not compatible. A properly organised staff of scientific workers is dealing with this and similar diseases, and on that staff graduates of the Dick Veterinary College are extensively represented. Report has it that there is great probability that a means of dealing with East Coast fever will soon be at hand. When this is accomplished the Dick Veterinary College will doubtless shine by reflected glory, for one of our graduates is at present pursuing a very promising line of investigation.

With the help of statistical tables, which are readily available, it is easy to show the decrease in contagious diseases. The prevalence or otherwise of non-specific disease is not so easy of demonstration. It is beyond doubt, however, that veterinary science, by disseminating knowledge regarding the maintenance of hygienic conditions, is doing much to lessen the more common ailments of farm and other animals. Agricultural science has done a very great deal to reform the methods of the farmer. The tiller of the soil has now only himself to blame if he follows the haphazard and unsatisfactory procedures of his forefathers, and reaps accordingly. But in the improvement of agriculture veterinary science can claim a share. The housing and feeding of animals has been studied not only from the purely scientific but also from the economic point of view. It has been demonstrated that there is a right and a wrong way of regarding the animal machine from the point of view of the economist.

In a further very important direction also science is helping agriculture. Breeding is being slowly raised from a process in which chance played the greater part to one in which there may be much certainty. The immortal if muddle-headed Mr. Tulliver was doubtless voicing the impression of most, if not all, his contemporaries when he said: "That's the worst on't wi' the crossing o' breeds you can never justly calkilate what'll come on't." Without wishing to arrogate to science more than is her due, and while admitting that scarcely more than the fringe of the subject has been touched, it may be claimed that the very juvenile science of genetics has already justified its existence, and will, beyond doubt, be of inestimable assistance to the breeder of the future. There can be little doubt that, at no very distant time, it may be possible to "justly calkilate what'll come on't" when certain breeds and individuals are crossed.

The conviction that medical science, veterinary no

less than human, must of necessity step aside from its purely curative function and give due regard to preventive measures, is of no new origin. For long it has been felt that preventive medicine had a great future before it, and it is becoming daily more evident that the conviction was well founded. Preventible disease is decreasing; with the more general adoption of hygienic measures it is safe to prophesy that it will continue to decrease. The study of the principles of immunity and their application also make for prevention in no trifling degree.

When disease does effect a lodgement, modern therapeutics—not forgetting serum-therapy—constitutes a powerful weapon whereby the practitioner may stay its ravages. Without doubt the veterinary surgeon of to-day is more fortunate in his equipment than were his predecessors, and not least so in the possession of medicaments, unknown to those who went before him, which have received such attention at the hands of investigators as has removed their use from the realm of empiricism.

In the immediate future, even more than in the present, it will be necessary for the veterinary profession to take a large share in the work of that organisation which has been evolved for the preservation of the health of the people considered as a community. During recent years it has become more and more apparent that the veterinary officer has a function in public health administration scarcely less important than that of the medical officer. It is clear that the health of the community is constantly menaced by danger of a double origin. Not only may disease and death have a human source, there is an animal source as well. Some diseases, such as glanders and anthrax, may be conveyed from animals to man by accidental inoculation. Other specific diseases, such as tuberculosis, may be transmitted to the human subject by the consumption of unsound meat and milk. From his knowledge of all the phases of disease in animals, no one is better fitted than the veterinary surgeon to assist in the safeguarding of man from disease of animal origin.

In most large towns—shall we say in towns blessed with enlightened authorities—there is a staff of efficient and specially trained veterinary officials. The value of their services cannot be put into figures, but in a town like Edinburgh we can say that it is through the instrumentality of highly competent veterinary inspectors that we eat sound meat and drink wholesome milk.

The day is not far distant when veterinary public health officers will form a considerable proportion of the profession. That these men must continue and amplify the work they have been doing for some time past has been emphasised by the recently published Final Report of the Royal Commission on Tuberculosis. In 1901 a Royal Commission was appointed in order that three questions regarding tuberculosis might be answered if possible. One of the questions was whether the disease in animals and man is one and the same. This has been answered in the affirmative, so also has the question whether animals and man can be reciprocally infected with it. Of the three questions the third is of supreme importance from a public health point of view, and was stated in these terms: "Under what conditions, if at all, the transmission of tuberculosis from animals to man takes place, and what are the circumstances favourable, or unfavourable, to such transmission." The Report of the Commission, upon which sat one of the most eminent members of the veterinary profession, a graduate of the Dick College, may be allowed to answer the question largely in its own words. "Only rarely has a pulmonary lesion in adult man yielded the bovine bacillus." But "our experience of abdominal tuberculosis in the human subject has been very different, especially as regards children. Of young children dying from primary abdominal tuberculosis, the fatal lesions could in nearly

one half of the cases be referred to the bovine bacillus and to that type alone. In children, too, and often also in adolescents, suffering from cervical gland tuberculosis, a large proportion of the cases examined by us could be referred to the bovine tubercle bacillus." "Whatever, therefore, may be the animal source of tuberculosis in adolescents, and in adult man, there can be no doubt that a considerable proportion of the tuberculosis affecting children is of bovine origin, more particularly that which affects primarily the abdominal organs and the cervical glands. And, further, there can be no doubt that primary abdominal tuberculosis, as well as tuberculosis of the cervical glands, is commonly due to ingestion of tuberculous infective material." "The evidence which we have accumulated goes to demonstrate that a considerable amount of the tuberculosis of childhood is to be ascribed to infection with bacilli of the bovine type transmitted to children in meals consisting largely of the milk of the cow." "But it must be remembered that we have found cases of tuberculosis in adult man sufficiently extensive to incapacitate the patient from the ordinary duties of life, and in two instances ending fatally, in which we were able to attribute the disease solely to the effect of the bovine tubercle bacillus."

The extent of these quotations is justified by the imperative necessity that the public and public authorities should be informed, on every possible occasion, of the momentous conclusions arrived at by a body of scientific men who have devoted their energies to the matter for the past ten years. With no uncertain voice have they made it clear that the services of the veterinary surgeon are needed—and urgently needed—in order that that much and naturally dreaded disease, tuberculosis, may be exterminated. For the sake of the children alone, if not also for the sake of adolescents and adults, tuberculosis in animals must cease to exist, and in the work of bringing about this eminently desirable state of affairs the veterinary officer of health, as well as the veterinary surgeon in general, must take a part. One more quotation from the Commission's report. "In the interests therefore of infants and children, the members of the population whom we have proved to be especially endangered, and for the reasonable safeguarding of the public health generally, we would urge that the existing regulations and supervision of milk production and meat preparation be not relaxed; that on the contrary Government should cause to be enforced throughout the kingdom food regulations planned to afford better security against the infection of human beings through the medium of articles of diet derived from tuberculous animals."

In view of the fact that fresh fields of activity are opening up for the veterinary surgeon both at home and abroad, no effort must be spared to keep the veterinary schools abreast of modern requirements, or rather one should say that the schools must be ahead of present needs in order that there may be a suitable margin of preparedness for subsequent developments. The present is a momentous period in the history of veterinary science in general, and particularly in Scotland. The next few years, it is confidently expected, will see such changes as will render it certain that the Dick College will advance in its position as one of the leading veterinary schools of Europe. The governing authorities are alive to the fact that the modern veterinary graduate must have a very different training from that received by his predecessors. Not only must he possess a first-hand knowledge of the more ordinary branches of his profession; he must be prepared to enter the ranks of those specialists who are so rapidly increasing in numbers. The graduate must not be content to have been spoon-fed by his teachers. He must have seen things for himself, *i.e.*, he must have done practical work in the laboratories and in the hospital, in the stable, the

byre, and the kennel. He must know something of veterinary public health administration. He must, in short, be ready with a substantial foundation upon which to erect a super-structure of knowledge for utilisation in his work as a general practitioner, as a member of the Army Veterinary Service, as a public official, either at home or abroad.

This means that the veterinary schools must expand their accommodation and equipments; must not relax in any degree their efforts to provide their students with a sound preliminary professional grounding, must be in a position to meet future calls upon their resources.

It must not be forgotten that to the schools look the practitioner, the animal owner, the agriculturist, and the general public for those additions to knowledge which shall make for increased efficiency of the professional man, which shall produce diminution of animal disease, and which shall ensure greater safety of the community from diseases and dangers of animal origin. Great though the recent advances of science may have been and many the secrets which have been probed, there is no fear that the scientist will imitate Dr. Busby and decline to remove his hat in the presence of the King for fear that the by-standers may not note what a great man he is. That which has been done merely serves to give some feeble indication of how much remains to be done, and engenders a feeling of humility rather than pride. There can be no resting on our oars. We must pull towards the light. The schools, therefore, in addition to being places where students are trained, must also be in a position to give habitation and encouragement to those who are prepared to devote their time and energies to the elucidation of problems the solution of which can but be of benefit to their fellow men.

AN UNUSUAL CASE OF POLL-EVIL.

A brown cart mare had been treated several times for a slight swelling over the region of the poll; being an extremely difficult animal to control, no surgical treatment was adopted until absolutely necessary. The swelling would break, discharge a small quantity of pus, then disperse, and the animal would work for some considerable time until the swelling appeared again. She was recently admitted to infirmary with a much larger swelling than usual, which broke and discharged a fair quantity of pus; the mare would not submit to handling of any sort, so we decided to cast and operate.

The animal was chloroformed and a probe passed from a sinus on top of poll, the direction of which was downward and forward. On attempting to open this outward so as to secure drainage the knife came in contact with bone. We were completely at a loss to understand the anatomical condition, it seemed quite impossible, however, to secure adequate drainage, the ligament was curetted and the animal allowed to rise, which she did without much trouble. In about 24 hours she was down in the box and unable to rise; we then suspected that we had probably got into communication with the spinal cord. The mare was destroyed with a thoracic injection of hydrocyanic acid.

Post-mortem.—The ligamentum nuchæ was diseased, but not to any great extent: there was,

Lateral aspect.

AN UNUSUAL CASE OF POLL-EVIL.

To illustrate case by H. D. Jones, M.R.C.V.S.

however, a fairly recent bony deposit on the occipital bone, there was also a recent deposit of bone on the floor of the spinal canal between the occipital bone and the atlas. The photograph of the posterior aspect of skull shows the canal into which the probe was passed—the knife was probably on the floor of the spinal canal. The atlas was completely fused to the occiput, no condyles could be seen, and the right styloid process was ankylosed to the wing of atlas. No movement of any sort was possible between the skull and atlas, the angle at which the atlas was fixed is peculiar, as shown in photograph of lateral aspect.

GASTRIC AFFECTIONS OF RUMINANTS.

As Mr. E. Wallis Hoare has invited opinions re the gastric diseases of ruminants, from his fellow practitioners, I give my opinions thereon for what they are worth, and they are the result of many years practice, and of a particular interest in cattle practice. I am quoting facts and not writing from book reference. We are students always, and I am always happy to learn something from my professional brethren—an interchange of opinion and of experience gleaned from long years of practice is a good thing for us all, as we are apt to get into certain grooves in diagnosis and treatment which, to many old practitioners, are as the laws of the Medes and Persians, which altereth not.

A good book on cattle pathology is much needed, particularly now that horse practice is on the wane. Cattle is perhaps not so clean as horse practice, and is not always as easy of diagnosis and treatment, but it is quite as lucrative, no motor car will oust the cow or sheep, so it behoves the coming V.S. to give more time to the study of the diseases of cattle and sheep, and even poultry and pigs. I hope success will attend Mr. Hoare's efforts and that his book will run through many editions.

Now as to Mr. Hoare's queries.

No. 1. Does impaction of the omasum occur as a disease *per se*?

My experience is in the negative. I have never in all the post-mortems during 34 years experience seen any but a dry condition of this part of the digestive tract of the bovine, both in health and disease. Of course there are degrees of dryness, but have never seen them really soft. I think it quite possible that the contents of the omasum may be dryer where inflammation of the abomasum exists, due no doubt to retention of its contents while the function of the true stomach is in abeyance.

I quite agree with other practitioners that purgatives given in excess have a very deleterious effect. I often wonder how bovines stand as much dosing with physic of various kinds as they do without fatal results, it is no uncommon thing to hear of cattle getting a stone of treacle, 2 or 3lb of salts, Ol. lini. by the quart, currants, rancid bacon, sundry pounds of butter, etc., and yet, in spite of all this

treatment the animal does not *always die*. I expect the major yart of this mixture lies dormant in the rumen; a certain amount of absorption no doubt takes place, but very little acts on the other stomachs and intestines. We were taught that fluids administered *slowly* by the mouth passed on to the reticulum, but I believe from post-mortem evidence that the bulk passes directly into the rumen, a part may pass on to the reticulum and act as a purgative.

The digestive organs of bovines are wonderful in their operation. The rumen I look upon as a reservoir to collect all that is eaten to satisfy hunger until that craving is satisfied; rumination then takes place, and the reservoir is gradually emptied by the beautiful and complex action of the reticulum, etc., there is no doubt that a certain amount of roughly masticated food finds its way into that viscus, and from thence passes on by an automatic process to the oesophagus and mouth where rumination takes place, and then the mixture of this masticated food with saliva, etc., passes on to the omasum, and there undergoes a process of squeezing, and absorption of the more fluid parts, the rest passing on to the abomasum and intestines.

The terms "Murrain," "Dry murrain," "Red Murrain," "Blain," "Gloss anthrax," "Worm in the tail," etc., I am afraid I am lamentably ignorant of, and I hope Mr. Hoare will, in his new book, treat them as "Terminological inexactitudes," and beneath the notice of an up-to-date treatise on cattle diseases.

Query No. 2. "Gastritis." This disease is not uncommon, and in my experience, both acute and subacute, and in the acute form is undoubtedly very fatal. The causes are certainly very obscure in many cases, but I am quite of opinion that it is due in most cases to errors of diet. Cold is another cause; changeable weather, standing in water when heated, etc. I have known it follow the animal being fed on too great a quantity of mangolds, soya cake, rich fog grass, acorns, potatoes, white turnip tops, decomposing turnips, and in some cases to some unaccountable herbage. I had cases recently where several head of cattle died from inflammatory disease of the abomasum and intestines with effusion of blood, they fed on a certain pasture and for two years running in the month of August the same disease appeared. I reported the case to the Board of Agriculture, and a veterinary inspector was sent down to investigate the disease, and although a post-mortem examination was made on a beast which has just died, and I sent the blood of one that was ill to the laboratory, no definite diagnosis was made. Brackens and tormentil were suspected as the cause, but on cattle being fed on these plants at the laboratory at Alorton, negative results were obtained.

In the case of inflammation of the abomasum from eating acorns, mangolds, soya cake, white turnip tops, and decomposing mangolds and turnips, and potatoes, I believe it due to some irritant in the composition of these foods, or it might be called a toxin. I have heard that white turnip tops and mangolds contain a certain quantity of oxalic acid, but have not been able to verify this.

I have seen brain and nervous symptoms in cases of abomasitis, the animal showing great excitement and distress, a rise of temperature taking place in most cases: there is generally a complication of enteritis, the contents of the intestines often being sanguineous—this state, of course, being found post-mortem.

I always give aperients in repeated small doses (but never large doses of strong cathartics), followed by treatment of symptoms.

In impaction of the rumen, which occurs from many causes, chiefly, I believe, from a gluttonous beast over-eating itself, and in some cases from drinking too much very cold water. I rely on oft-repeated doses of aperients combined with tonics of various kinds, and if tympanitis occurs my sheet anchor is *Ol. menth. pip.*, *Tinct. nux vomica*, and *Spts. amm. arom.*, and these have, as a rule, the desired effect. The trochar and canula and rumenotomy as the last resort.

When paralysis of the digestive tract takes place, the cases take a lot of bringing round, and the cause of death is often due to this state of things as the post-mortem reveals nothing to account for death. During inaction we often have cases of indigestion there is no doubt.

No. 4. "Spewing the cud." This I have seen often, but could never satisfy myself as to the cause. I am always suspicious of nerve lesion, and treat accordingly; they generally recover the normal cud with this treatment. I once had a case that was most intractable and went on for weeks, the trough being half full of half masticated hay and fluid. I thought it a hopeless case, but all at once it stopped, and the cow regained its natural cud and got fat; it might have been due to the bursting of an abscess. Casting the temporary teeth may account for some of these cases. It is a common trouble in calves, but they generally recover as they get older.

ABSTRACTS FROM FOREIGN JOURNALS.

CEREBRAL EMBOLUS PRODUCED BY "STRONGYLUS VASORUM."

Capdebelle and Hussenet record (*Revue Vétérinaire*) the case of a fox-terrier bitch, fifteen months old, which for eight days refused all solid food, only taken a little milk and vomiting it almost immediately. Suddenly she manifested epileptiform attacks, showing rather marked prostration, contraction of the muscles of the limbs, twisting of the head upon the neck, oscillation of the eyes, salivation, and emission of urine. The attacks were repeated frequently in the day and caused the death of the animal.

Post-mortem, lesions of acute gastro-enteritis were found. The lungs were filled with miliary granulations of a greyish colour and a firm consistence; in certain parts of the lung more voluminous nodules were seen. Histological examination

of cut sections showed that each nodule had developed in a small branch of the pulmonary artery containing strongyles, which proved to be specimens of the *Strongylus vasorum*.

The brain was examined, and its left hemisphere showed a rounded brown patch, about four-fifths of an inch in diameter, very slightly depressed and softer in consistence than the surrounding tissue. Incision of this revealed a hæmorrhagic focus, containing a clot the size of a large nut, and extending as far as the roof of the lateral ventricle. Microscopical examination showed a strongyle embryo, still living, in the midst of the clot.

This unexpected discovery explained the pathology of the symptoms which had been observed. The centres of pulmonary strongylosis, which had been unsuspected during the life of the animal, had allowed the escape of a strongyle embryo, which had gained the left side of the heart, had thus become launched into the general circulation, and had become arrested in a capillary of the brain.—*Annales de Méd. Vét.*

(Without a careful post-mortem examination this case might easily have been set down as "ptomaine poisoning," arising from digestive disturbance.—*TRANSL.*)

BISMUTH INJECTIONS INTO FISTULÆ IN VETERINARY PRACTICE.

Bauza (*Revista de Méd. Vét. Montevideo*) gives an account of the now well-known "Beck's method" of treating old fistulæ, which consists in the injection of a mixture of wax, vaseline, paraffin, and subnitrate of bismuth. He reports four cases in which the method gave him excellent results. One was in a young Normandy bull having an abscess of the left side, which had been opened and treated without success by various antiseptics. Recovery took place in fifteen days after two injections. The second was in a Dutch cow having an abscess of the shoulder, which also had been treated without success. Treatment by Beck's method led to recovery at the end of twenty-five days after only one injection. The third was in a draught horse having a voluminous hæmatoma in the region of the haunch, which had been opened, became infected, and resisted ordinary methods of treatment. Recovery took place under Beck's method after a single injection. The last case was in a mule, the pectoral region of which bore an abscess having a fistulous course, originally caused by a pointed foreign body. This recovered in eleven days under Beck's treatment by means of a single injection.—*Annales de Méd. Vét.*

TUBERCULOSIS OF THE TESTICLE AFTER CASTRATION BY CRUSHING.

Gergely, of Hatvan, records (*Allatorvosi Lapok*) the following case of an ox, which, when castrated, had been operated upon by the method of crushing the testes. At the age of eight years, this animal was brought to the slaughter-house, it being said that a veterinary surgeon had advised his destruction on account of nephritis. The ox's temperature was then 104.3° F., and the pulse counted 56 per

minute. Bleeding was very free after division of the cervical vessels.

Post-mortem, the peritoneal cavity was found to contain 15 litres (about 26 pints) of a reddish transparent fluid; while the pelvic wall showed numerous tubercles ranging from the size of a millet seed to that of a bean.

The spermatic cords were swollen to the thickness of the human arm, with the remainder of the testes attached to their ends. The latter—each of which was about the size of a child's head—when cut into, showed a marbled surface of section beset with numerous caseous foci.

Castration by crushing of the testes had established a *locus minoris resistentie*, in which tubercle bacilli (probably coming from the intestine into the circulation in the first place) had collected and set up tuberculosis of the testes.

The mucous membrane of the bladder also showed some reddish-black coral-like growths. No tuberculous lesions were demonstrated in the kidneys, spleen, bones, and other organs.—*Berliner Tier. Woch.*

INFECTIOUS HEPATITIS OF SWINE.

Josef Tautenui describes (*Allatorvosi Lapok*) an acute infectious disease of swine, leading to death in from 9 to 48 hours, which he has observed. High fever, loss of appetite, prostration, and dyspnea are the symptoms during life; while tympany and putrefaction appear very soon after death. The anatomical lesions are—hyperemia of the large intestine, sanguineous infiltration of the gastric mucous membrane, swelling of the spleen, and a special appearance of the liver, which is soft and swollen, but later becomes almost elastic, and is beset by many vesicles. The lungs are œdematous, and the heart shows fatty degeneration.

The disease is incurable, and generally appears in places where swine fever is prevalent. It may be distinguished from swine fever partly by its rapid course, and partly by the hepatic lesions. It is differentiated from swine erysipelas by the fact that the redness of the abdominal skin which is noticed in its later stages is a hypostatic alteration, whereas in swine erysipelas the skin shows inflammatory symptoms. Moreover, the hepatic lesions are not seen in swine erysipelas.

Microscopically; a bacillus resembling that of malignant œdema is demonstrated in the liver.—(*Berl. Tier. Woch.*)

W. R. C.

SOUTHERN COUNTIES' VETERINARY SOCIETY.

MEETING AT ALDERSHOT.

A meeting was held on Thursday, Sept. 28th, and was rendered additionally interesting by the kindness of the General Officer Commanding in Chief (Aldershot Command) in affording an opportunity for the inspection of the Army Veterinary School. The business meeting was held at the Royal Hotel, Mr. S. H. Slocock, of Hounslow, presiding in the absence, owing to illness, of the President, Mr. W. Hunting, and the following mem-

bers and visitors also signed the attendance book: Prof. G. H. Wooldridge, London; Messrs. H. A. Archer, Southsea; W. Burt, junr., J. H. Lockwood, Brighton; G. W. Bloxsome, Harold Leeney, W. K. Stuart, Hove; B. H. Benson, Reading; W. Caudwell, Chertsey; W. A. DellaGana, Southampton; C. W. Howard, Dorking; F. G. Samson, Mitcham; H. Smith, J. Alex. Todd, Worthing; D. Wyllie, Staines.

Visitors: Major A. C. Newsom, A.V.C., London; Messrs. C. Barnwell, H. G. Brookman, A. N. Cannon, Worthing; W. H. Brown, W. W. Henderson, and A. Whitelaw Carter.

On the proposition of Mr. Burt, seconded by Mr. Smith, the minutes of the last meeting as published in *The Veterinary Record* were taken as read and confirmed.

The Hon. Sec. reported that he had that morning received a telegram from Miss Hunting in the following terms:

"My father is ill in bed. He desires to express his regret. He especially wished to see the Army School and take part in the discussion on Mr. Bloxsome's paper."

The CHAIRMAN said he was sure they all regretted the absence of their President, and that it would be their wish to convey this regret to Mr. Hunting. He suggested that they should ask Mr. Todd to write a letter to that effect.

Prof. WOOLDRIDGE: And also express our hope for his speedy recovery.

Mr. STUART seconded, and the proposal was at once agreed to.

Apologies and expressions of regret at inability to attend were also announced from the following: Col. F. Smith (A.V.S.); Prof. F. Hobday; and Messrs. E. Whitley Baker, R. Burt, A. L. Butters, C. J. Callow, W. A. Collins, J. B. Dier, Haywood Jeffries, J. B. Martin, W. F. Maynard, F. Marks, D. Pugh, R. Roberts, C. Roberts, W. Shipley, C. H. Spurgeon, R. A. Thrall, F. T. Walder, and A. Whicher.

A letter was read from the Editor of *The Veterinary News* inviting subscriptions towards the fund which is being raised to assist Mr. William Kirk in his appeal against the action raised by the London County Council to compel veterinary surgeons to pay for the use of the College crest.

Mr. DELLA GANA proposed that the matter rest where it was and that they take no action, and this was seconded by Mr. Burt.

Prof. WOOLDRIDGE, on the other hand, suggested that they should give a subscription to the fund. He did not regard this at all as a personal matter. For himself he should not think of using the crest, but there were other members who might wish to do so, and he thought they ought to support them.

Mr. Burt, Mr. Stuart, and Mr. DellaGana, however, all spoke strongly against taking any action in the matter.

Prof. WOOLDRIDGE, in the circumstances, announced that he would not press his amendment to a vote.

Mr. DellaGana's motion not to take any action was accordingly put and carried by five votes to two.

A communication from Prof. Gofton *re* the scheme for the amalgamation of Veterinary Societies, was on the suggestion of Mr. Burt, ordered to be placed on the agenda for consideration at the next meeting.

NOMINATIONS.

Messrs. W. W. HENDERSON, of Haslemere, and T. A. B. COCKSEGE, of Emsworth, were nominated for membership, on proposition of Mr. Archer, seconded by Mr. Burt.

The selection of a place for the next meeting was next considered, and on the proposition of Mr. Burt, seconded by Mr. Stuart, it was decided to meet in London during the Cattle Show week, as in former years.

"SOME DEBATABLE POINTS OF UNSOUNDNESS IN HORSES."—By Mr. GERALD BLOXSOME. (Adjourned Discussion).

Mr. W. A. DELLA GANA reopened this discussion, and read the following contribution :

All of you have no doubt seen the very interesting and practical paper by Mr. Gerald Bloxsome on "Some debatable points of unsoundness in horses," read at a recent meeting of this Society. The points raised by the essayist for discussion, refer mainly to the definition of soundness and unsoundness ; and its relation to splints, sidebones, ringbones, the abnormal development of processes of bones, and spavin, most of them resulting from some form of otitis.

With regard to a definition of the term "unsoundness," I think the simplest one I know of, is—any deviation from the normal, which is, of course, purely a classical one. A more practical definition, I venture to say, would be, "Any defect in the animal likely to, immediately, or at any future time, prevent it from doing that work which might be required of it."

We know that there are few horses over five years old which do not exhibit "splints"—the most common form of exostosis in equines. Many foals were born with them. Much has been written on the subject of splints, and notwithstanding, we still look upon them as an unsoundness, and it remains for us to advise our clients accordingly. I do not think that there is a more troublesome cause of intermittent and severe lameness in its earlier stages in horses than due to splint formation. Once a splint always a splint, and I quite agree with the essayist inasmuch that he would preferably purchase a horse with a splint than a horse without one, splints are undoubtedly an unsoundness and should always be mentioned in certificates.

Most of you who have had experience amongst heavy horses will appreciate Mr. Bloxsome's remarks upon the vexed question of sidebones, a fruitful and, in my opinion, a frequent cause of unsoundness and lameness in horses of the heavier breeds. I believe that some practitioners go to the extent of not considering this as a serious condition at all, provided that the foot be a large and open one. On the contrary, I have found sidebones a very frequent cause of lameness in heavy cart-horses, especially when overtaxed with work. We know of horses with immense sidebones doing their work continuously and well without showing any lameness whatever. My contention is that a horse affected with sidebone, so long as the feet are not subjected to lateral strains such as for instance the horse bringing the foot hard down upon an uneven surface, it will continue in work free from lameness.

I have not yet seen a light horse, hunter or hackney, affected with sidebone free from stiffness or lameness, but I will not deny the utility of such an animal. We know that many military horses are annually cast as useless for being affected with sidebone.

Ringbone, to my mind, is a very much more serious condition than the foregoing, and a frequent cause of lameness in all breeds of horses.

It is in the earliest stages of development when we find the greatest difficulties in arriving at an exact diagnosis. The so-called incipient ringbone is responsible for much difference of opinion.

I quite agree with Mr. Bloxsome regarding his remarks upon the coarse development of the processes on the distal ends of the os suffraginis, a condition which occurs mostly in underbred horses. The only possible means to arrive at a definite decision is to examine the opposite leg, and should the condition prove to be symmetrical, or there be a general defective conformation of the whole of the extremities, we might then express a guarded opinion.

Lastly, but not least, the essayist refers to that hardy annual, that burning question, "A spavin or not a spavin?"

No bone disease of equines has in past times, and I think I can safely assert in future times also, has, and will, excite as much controversy as this one.

Apparently what we have to decide is "When is a spavin not a spavin?" for any enlargement on the inner side of the horse's hock, no matter of what nature, is generally referred to as a spavin.

This question, gentlemen, will, I think, alone provide ample matter for discussion, and should we be able to arrive at some definite conclusion, then I think we will have reason to congratulate ourselves.

DISCUSSION.

The CHAIRMAN said he hoped the discussion would be kept alive, for he was sure the paper warranted it. There was just one stipulation he ought to make perhaps. They were expected at the Army Veterinary School at half-past three, which did not give them very much time, and if each of them would confine his remarks, say to five minutes, it would give them all a fair chance.

Mr. BURT remarked that there was one or two points he would like to mention, or rather to obtain information upon, if that were possible. Mr. Bloxsome said he could honestly say that when a sidebone was so formed that one could positively state that it was present, he had never seen the horse suffer from lameness from it.

Mr. BLOXSOME : When you can feel the sidebone above the coronet.

Mr. BURT : You have never seen a horse lame from sidebone?

Mr. BLOXSOME : No.

Mr. BURT, continuing, remarked that a large proportion of his practice had been among heavy horses, and while he had never been able to say that the animal was lame from sidebone when he could not discover it, they had suggested there was an inflammation of the coronet which was possibly the commencement of sidebone. In his experience forty per cent. of the lameness of the fore feet in cart horses was due to sidebone, either formed or sufficiently palpable for them to be able to say definitely it was sidebone. Personally he was a great believer in firing horses for sidebone, and he had found they generally came up sound again after five or six weeks. Of course, the trouble might not have been due to sidebone, but if it was not it was rather a remarkable coincidence. One might say, he supposed, that in ninety-five per cent. of the lameness there was no veterinary surgeon who could speak positively as to the cause, but when they started diagnosing by a sort of negative reasoning, commencing with the shoulder downwards, and found at last the presence of sidebone, he thought they would admit that at all events they had then got something to go upon. To take another point, Mr. Bloxsome had remarked on the fact that sidebone did not appear to be so common amongst hunters, but here again it was very difficult to disprove a statement of that kind. He had seen one or two light hunters used for harness work that had sidebone, and they had been distinctly lame. They had nothing else the matter with them, and the only assumption one could consequently form was that they were lame from the presence of sidebone. Mr. Bloxsome told them the conclusion he had arrived at was that although they must clearly class sidebone as an unsoundness, still in the state in which they were able to recognise it it did not cause lameness, but if it did not cause lameness why class it as an unsoundness.

Prof. WOOLDRIDGE asked in what way Mr. Burt fired for sidebone.

Mr. BURT : Either puncture firing or line firing.

Prof. WOOLDRIDGE: The reason I asked is that a so-called modification of Smith's operation is sometimes practised with success.

Mr. SAMSON had not read the paper very minutely, but there were one or two points he certainly could not agree with Mr. Bloxsome upon. It might be, however, that their practice had been among a different class of horses. With regard to the liability to an action at law, he had always understood they could not compel a man to take a horse back, the proper way was to resell the animal and then bring an action to recover the difference in the price. With reference to splints, Mr. Bloxsome said a good deal was made of the position, but that when once formed and the horse went sound he did not believe it made the slightest difference where it was placed. In his (the speaker's) opinion if they got a splint well up under the knee it did make a difference—and a radical difference, for that horse was more than likely to be unsound, and very lame for the rest of its natural life.

Then, again, Mr. Bloxsome said he believed in the statement once made by Professor Macqueen that the latter had never seen a horse lame from sidebone, but he (Mr. Samson) certainly could not agree with that. In the course of his experience he had seen many cases of lameness from sidebone and nothing else, and the lameness had unfortunately lasted—sometimes much to his cost. With firing for sidebone he had had very good results, but he found the majority of people put the firing off until the sidebone was too well formed. For firing to be any good in cases of sidebone it should be done early, and then, he thought, it was quite immaterial whether they used the deep puncture firing or the line firing. To take another paragraph in the paper, Mr. Bloxsome said he could call to mind many instances of brilliant performers amongst hunters keeping perfectly sound with large sidebones, and he quite believed that. On the other hand there were many cases of sidebone which went very lame and kept lame, particularly where the ground was a bit hard.

Then, again, Mr. Bloxsome stated that true ringbone, where the joint was involved, always caused lameness, but he did not agree with that. It certainly did in many cases, but in many other cases ringbone did not cause lameness any more than splints. As to calling a horse sound, he thought it was a very bad practice to state whether it was sound or unsound. The best plan was to say that in their opinion the animal was practically sound, or was a useful animal and one they could advise their client to purchase, but to point out that it had got splints or sidebones as the case might be, and that these might possibly cause trouble in the future. If they gave a definite certificate that a horse was sound it was ten to one they would have the animal sent back to them sooner or later.

Mr. ARCHER very much doubted whether the fact of putting on a certificate their opinion as to whether a horse was sound or not screened them at all in point of law, because everyone knew the certificate represented their opinion, and the fact of their being qualified to give an opinion bound them in point of law to that opinion. He had seen a good many cases of sidebone in which it had caused lameness, both in heavy and light horses. One reason why they were an unsoundness, or should be considered such in his opinion, was this—especially when they were associated with ringbone—they caused a certain rigidity of the limb resulting in damage to the flexor tendons. It interfered with the natural action of the limb, and they got an extra strain on the flexor tendons which very often caused lameness there. With regard to splints, he was certainly convinced that the position had a very material influence on the question whether it caused lameness or not. When a splint was well forward on the bone so that they could see it, it was not nearly so likely to cause lameness as

when it was further back. Also when it was well up under the knee they almost always got lameness. It was quite possible to have spavin without causing any actual lameness, but there was usually a general stiffness of the joint, if not actual lameness, and any animal with spavin he considered ought to be classed as unsound. Personally, he generally mentioned that such and such things were present, but that otherwise he saw no unsoundness. He thought it was the best way to safeguard oneself from giving a definite opinion. They implied that it was unsoundness but did not actually say so. On the other hand, if there was no interference with the action of the animal he thought they might fairly give a certificate of soundness.

Prof. WOOLDRIDGE did not know but that they were getting a little off the track in discussing the method of writing certificates for unsoundness, although while they were on this matter he must say he did not think it was wise for them to be over cautious in the wording of their certificates. He meant that they should form an opinion and then write that opinion down definitely and clearly, and he did not think Mr. Archer's method was to be recommended. On the question of spavin he quite agreed with Mr. Bloxsome, although he did not know whether he had introduced the term "spurious spavin" seriously. All of them who had had any experience of horses and the examination of them would have examined hocks that had been uneven, but which had given no direct indication of exostosis, and which in the light of after experience they had found to wear exceedingly well. If such a horse passed its trial without showing any interference with its action he mentioned the fact that it had "odd hocks" but did not use the word spavin at all. He did not think it wise to use the term "spurious spavin." Either the animal had spavin or it had not. As regards the legality of certificate he believed that if as professional men they exercised a proper amount of skill and care in the examination of any animal submitted to them, and they came to a certain conclusion, they were not liable in law for damages even if it should be found out afterwards that that conclusion was not correct.

He did not know whether he could agree with Mr. Bloxsome with regard to the effect of splints. He believed he suggested in his paper that one could not legally certify a horse as being sound when splints were present. He thought they could.

Mr. BLOXSOME: You cannot.

Prof. WOOLDRIDGE: Well, if there has been any legal ruling on that point I should like to know it.

Mr. BURT: What is your definition of unsoundness?

Prof. WOOLDRIDGE: Any condition which interfered with the natural usefulness of the animal either at the time or at some future date. Prof. Wooldridge added that he did not suggest the definition mentioned by Mr. Bloxsome of being absolutely free from disease because if that was to be the condition he was afraid there was not a sound horse in the world and never would be.

The effect of sidebone he admitted was a very vexed question. He had seen a large number of horses in which sidebone had not interfered with their action, but he could not agree with Mr. Bloxsome that horses with well developed sidebone never went lame from that condition. It depended perhaps on what they would call lameness. He had seen horses with a decidedly cramped action, and he had regarded that cramped action as a phase of lameness, and as having been due to sidebone. Personally he should certainly class sidebone as an unsoundness, on the ground that it was impossible to say whether lameness would occur or whether it would not. He had been rather surprised to hear Mr. Bloxsome say that at least fifty per cent. of cart horses developed sidebone in studs where the animals had been carefully selected. He confessed that he had no figures to go upon, but he was surprised to

hear the percentage was so large. With regard to the treatment for sidebone he believed what was known as Smith's operation had produced as good results as any.

The CHAIRMAN remarked that before calling on Mr. Bloxsome for his reply, there were one or two things he should like to refer to briefly himself. The first was the definiteness, or indefiniteness, of the certificates which they gave. Personally he did not think it paid to give an indefinite certificate. If there was one failing which they had as a profession he thought it was this one of not being sufficiently definite when they were asked for their opinion, and they would generally find that the practitioners who were doing the best were those who gave the most definite opinions, although very often they might be wrong in those opinions. A man could make any number of mistakes and so long as he was sufficiently definite in his opinion he did not believe it really mattered much, but at the same time when asked to state whether a horse was sound or not, they wanted to allow a certain amount of latitude in the framing of their certificates, because the use of the word unsoundness might deter a client from buying an animal when as a fact the horse would be a very useful one for the purpose for which it was required. He should be inclined to say that in his opinion the horse was sound, adding that he noticed it had splints, but that in his opinion they were never likely to cause any trouble.

With regard to the position of splints, he must admit that that had a very great deal to do with the question. In his opinion a splint did not cause lameness for any length of time so long as it did not interfere with the natural action of the animal. Sidebone also caused lameness on its formation, but it did not follow that lameness would last. He happened to drop into a practice where there were a lot of heavy horses, and he noticed that although he tried to select horses that were free from sidebone he got a tremendous amount of lameness amongst them. In fact he believed he had less lameness in the horses with sidebone than in those without. He thought they sometimes lost sight of the fact that there was a sidebone connected with ringbone, and it was a very shrewd observer who could say a horse was free from ringbone.

Mr. BLOXSOME being invited to reply, remarked that it had been a matter of great gratification to him to have such a long and varied discussion on the thoughts he had committed to paper, but as the time was short he would endeavour to make his reply as brief as possible. The first point he wished to touch upon was that of the definition of unsoundness, and here he should like to say that the definition he had given them was not his own but was the one which was accepted in all Courts of Law. Mr. DellaGana he believed had suggested "any deviation from the normal" as a definition of unsoundness, but he could not agree with that, because a horse might have any number of malformations without its soundness being affected. With regard to sidebones, he fully expected there would be a great difference of opinion about the statement of Prof. Macqueen which he had quoted, but as he had explained he did not say a horse never went lame from it. What he did say was that if they went in the ordinary way of examination and saw a horse with sidebone when the process of ossification had got to that stage that they could feel the formation of the bone above the coronet, he had never yet seen a horse lame from it. Plenty of horses that had sidebone were lame, but that did not prove that they were lame for sidebone. There were many other troubles in the hoof which might be associated with lameness, and if they looked carefully and long enough they would generally find them. One of the most frequent causes of lameness connected with sidebone was low ringbone. There was nothing to be seen or felt,

but they might satisfy themselves by the use of cocaine, or other means, that the lameness was in the hoof, and by a negative process of reasoning they could put everything else out until they came to low ringbone. While the process of ossification was going on below the coronet it was only reasonable that the horse should go lame. No one could say definitely whether it was from the formation of sidebone, but it was quite possible it was. With regard to splints, and the wording of certificate, what he wanted to guard against was the giving of general certificates, such as saying "I examined a bay gelding and in my opinion she is sound." Certificates of that sort were of no practical value whatever, and if a dealer got hold of them they could be used for a dozen of bay geldings. They could not be too careful in getting all the recognition marks possible down on their certificate, and then he did not think they were called upon to say whether the horse was sound or unsound, because according to the law as it is to-day, a horse with splints is unsound. Prof. Wooldridge objected to the use of the term spurious spavin, but he only called it that for the purpose of his paper. They did not want to use the word spavin in any other way than for spavin. The question was to decide what was spavin. He quite admitted that was a difficult point, but what he wanted to draw attention to was that absolute symmetry was not necessary to soundness. All they could do was to exercise every care while they were examining horses where there was a difference in the size of the hocks.

On the proposition of the Chairman, seconded by Mr. DellaGana and Mr. Smith, a hearty vote of thanks was accorded Mr. Bloxsome for his paper, and a similar complaint to Mr. Slocock for presiding, proposed by Mr. Stuart, and seconded by Mr. Lockwood, brought the proceedings to a close.

CENTRAL VETERINARY ASSOCIATION (IRELAND).

A general meeting was held at O'Carroll's Hotel, Ballinasloe, on the 2nd inst. Mr. A. J. Moffett presiding. Present: Messrs. J. Nolans, Birr; E. A. Ryan, Strokestown; W. C. Patrick, Mullingar; A. J. Bolton, Athlone; A. J. O'Dea, Tuam; C. Tracy, Ballinasloe; and E. C. Winter, Limerick, Hon. Sec.

Letters of apology were received from the President, Mr. J. F. Healy and Mr. P. J. Howard, stating they could not travel on account of the railway strike. Apologies were also received from Messrs. M. Hedley and J. Holland.

The minutes of last meeting, as published in *The Veterinary Record*, were approved.

Mr. J. C. Doran wrote and regretted that he had not prepared a paper for the meeting.

A discussion took place on the fact of veterinary inspectorships, under the Contagious Diseases Act, and the Dairies, Cowsheds, and Milkshops Order, being given to laymen, where veterinary surgeons were available.

The Secretary was directed to collect information for the next meeting, from the various public bodies as to the numbers of these appointments and the emoluments they carried, with a view to again approaching the Local Government Board on the matter. Some of the members were of opinion that local veterinary surgeons should take the appointment even at a very small salary so as to retain them in the profession, and then apply for an increase of salary on showing the amount of work done.

The SECRETARY directed attention to the subscription list, many members being in arrears, and was directed to press the defaulters.

E. C. WINTER, Hon. Sec.

ROYAL (DICK) VETERINARY COLLEGE.

The eighty-ninth session was formally opened on Wednesday afternoon, Oct. 3. Sir William Turner, K.C.B. Principal of the University of Edinburgh, presided, and among others present were Dr. O. Charnock Bradley, Principal of the College; Mr. C. Price, M.P.; Sir Andrew McDonald, Emeritus Professor Chiene, C.B.; Treasurer Leishman, Col. Wardlaw Ramsay, and Mr. Robert Anderson, S.S.C., Secretary.

Principal Sir WILLIAM TURNER: We are met to-day under special circumstances, because since the end of the last session important changes have taken place in the staff of the College, and I think it right that I should say a few words in regard to those changes. In the first place Principal Dewar tendered to the Board of Management his resignation. Principal Dewar has been associated with the Veterinary College for I believe some twenty years, and for the last fifteen years he filled the important office of Principal. (Applause.) The Board of Management desire to express their acknowledgment of the services which Principal Dewar rendered during this long period of office. His resignation necessarily involved the re-arrangement of the staff. As his successor the Board have appointed Prof. Bradley. (App.) Those who have been students of the College during the years Dr. Bradley has been Professor of Anatomy know well the zeal he has shown in the discharge of his duties. (App.) But the post of Professor of Anatomy in the Royal (Dick) Veterinary College seems to be a sort of standpoint from which the anatomical professor may jump into a Principalship, for it happens that the Principal of the Veterinary College in London and the Principal of the Veterinary College in Dublin were predecessors of Prof. Bradley in the Chair of Anatomy in this College. (App.) Principal Bradley has now been appointed the lecturer in the University on that branch of Comparative Anatomy which refers to the domestic animals which you have studied in this College. Prof. Gofton has been appointed Professor of Medicine, and the Chair of Surgery which he held has been given to Mr. Ainsworth Wilson, while the lectureship of Hygiene has been filled by the appointment to it of Mr. Basil Buxton.

It is clear that the veterinary profession is now called upon to take a wide grasp of questions affecting the public health—the health of man as well as the health of animals. You cannot indeed dissociate the public health of man from the public health of the animal, because there are so many infectious diseases that the animal can and does transmit to man, so that human medicine and veterinary medicine have a very close alliance and association with each other. Therefore we must now look at the veterinary profession as a profession which is not only concerned in, if I may say so, the doctoring of animals, but which has to do with disease of various kinds in its wide aspects, embracing man and animals. (Applause.) But this study cannot be properly proceeded with unless the veterinary student has for his guidance and help adequate buildings, adequate equipment, and adequate staff of teachers. This important development of the subject with which you are especially concerned has been under the consideration of the Board now for a considerable time, and the first thing that we had really to decide upon was—Is it possible to obtain in this city a site which could be adopted for the building of a College in accordance with the present needs of veterinary medicine and veterinary science? Now I am happy to say that a site has been secured and paid for. (Applause.) Unfortunately I cannot say that we have sufficient money to erect the buildings at the present time, although I must acknowledge the great assistance that we have received from public bodies in Edinburgh, such as the Corporation of the City, the Carnegie Trust, the Highland and Agricul-

tural Society, and the Executive Committee of the recent Edinburgh Exhibition. (Applause.) We have also received valuable assistance from private friends. In the front of those friends I must name one of your own profession—Mr. MacCallum. (Applause.) Not only has he shown his love for his profession by endowing a Chair in the College, but he has still further given handsomely towards the erection of the buildings of the new College. (Applause.) Another friend has been Mr. C. E. Price, M.P., who from the beginning has shown a practical interest in the prosperity of the movement. (Applause.) It remains for me to state that the College has now become a Central Institution under the important Education (Scotland) Act of 1908, and as such we have a claim on the funds that are administered by that Department. I was happy to hear this morning that the Department has recognised the claim, and has already handed over to our Secretary a very handsome cheque. (Loud applause.)

[Principal Bradley's address appears on p. 229.]

Grouse Disease.—The Report of the Committee of Enquiry.

For close on a hundred years the private records and the reports of grouse shooting have contained mention of "disease," an epidemic—if the grouse world may be called a demos—which has done enormous damage. From time to time scientists have turned their attention to the subject; but, until recently, lack of organisation and combination of effort stood in the way of really effective investigation. Towards the end of the nineteenth century two theories as to the cause of grouse disease were chiefly favoured. These were evolved by Prof. Klein and Dr. J. Spencer Cobbold respectively. It was to probe these and other theories to the full that in 1904 a number of gentlemen formed themselves into a Committee of enquiry on Grouse Disease.

The Committee issued an interim report in 1908, and now the final report has made its appearance, published by Smith, Elder, and Co., at two guineas. When the excellence of the production, the illustrations being particularly good, the magnitude of the investigation, and the provision of the terms of reference that no public money be expended on the enquiry—the cost of which to the members of the Committee and private subscribers has been something over £4300—are taken into consideration, there seems reason for surprise that the price at which it may be bought is so small as it is.

Though Prof. Klein's theory was of later date than was that of Dr. Cobbold it may be well to consider this one first. Klein examined a large number of birds, some of which had died in emaciated condition, some in apparently good; and he came to the conclusion that "the congestion of one or both lungs, the congestion of the liver, the small dark spleen, and the patchy redness of the intestine and the peritoneum," and the presence of *Bacillus coli* in the lung and liver of infected birds, proved the true grouse disease to be a form of acute infectious pneumonia—something such, perhaps, as the pneumonic plague which assails the beaver in the streams to the east of Lake Baikal in Western Mongolia. The Committee began by thinking that Klein's disease was a fact, and spoke of it as the "true epidemic grouse disease." And in a few isolated cases that early were brought to their notice the Committee's field observers believed that the lesions described by him, with so much detail, were present. They thereupon, for the next week or two, awaited an inundation of dead birds showing similar lesions. But no epidemic occurred, and the inundation did not happen; and it became evident by degrees that there was something doubtful about the view which had been provisionally adopted.

Later it seemed to be proved clearly that, accurate

and painstaking as Prof. Klein had been in his work and description of what he had seen, his deductions were founded on a misconception. Dr. C. G. Seligmann found in birds that were obviously dying from "grouse disease" there was no dangerous ante-mortem infection of the lung or other tissues with the *Bacillus coli*, and no recognisable lesion in any organ of the bird except in part of the intestine. All the appearance of congestion and pneumonia in the lung were found to be due to post-mortem change alike evident in diseased and in perfectly healthy normal birds. The point was tested by taking a number of healthy pigeons and killing the whole of them at the same time with chloroform. The birds were numbered and opened on consecutive days, and the change in the appearance of the viscera was noted. It was evident that in every case where there had been extravasation of blood or serous fluid, owing to rough handling or damage by the knife in dissecting the pigeon, the tissues of the lung became black and took upon themselves precisely the same appearance that is seen in a grouse found dead upon the moor or examined some days after being shot. The appearance of pneumonia was evidently due to the soaking of the lung-tissue in decomposing blood and serum, and the post-mortem colonisation of the tissues by *B. coli*.

Cobbold's view, advanced just after the famous outbreak of 1872, was that the epidemic was entirely due to the presence in the pair of cæca—those parts of the grouse which correspond to the appendix in man—of large numbers, thousands, of small nematode worms, *Trichostrongylus pergracilis*; and while thinking Klein's the "true" epidemic, the Committee had no doubt that these internal parasites had been responsible for a considerable share of mortality, and the outbreak of 1907 had given them an excellent opportunity for collecting data.

Having come to the conclusion, then, that the "infectious pneumonia" theory was untenable, from 1908 onwards the following points were studied especially: (1) The life history of the *Trichostrongylus pergracilis*; (2) the life-history of the other internal parasites infecting the alimentary tract of grouse; (3) the protozoal parasites infecting the alimentary tract and blood of grouse; (4) the bacteriology of grouse; (5) the various insects found on the moors, both from the point of view of insect-borne disease and the view of food; and others.

It is just possible that the committee's investigators never came across the genuine "Grouse disease"; but, apart from that question, all the outbreaks of disease that have come under their notice—and some 2,000 birds were examined—can be ascribed either to strongylosis or to coccidiosis, the latter the result of the presence in the duodenum of *Eimeria* (*Coccidium*) *avium*—a parasite discovered during the investigations by Dr. Leiper.

Cobbold differed from Klein in one very important respect—viz., that he distinctly indicated that he did not observe any example of a grouse dying in good condition and without having lost weight.

"It is quite clear," say Dr. E. A. Wilson and Mr. A. S. Leslie in their account of the work of the committee, "that one of the most important signs of disease . . . is loss of weight. And this loss of condition, even to emaciation, which follows on strongylosis, is a character to which full prominence is given by all writers about "Grouse Disease," though no measurement of actual weights had ever been recorded so far as was known before the present inquiry began its work. The omission to record weights is all the more to be regretted because the chief characteristic of the only other form of "Grouse Disease" which has been reported is the fact that the weight of birds that have succumbed to it remains normal.

The good condition, however, may have been so

called not as the result of actual measurement but on the bird's appearance of good feather and normal weight when taken in the hand as it lay dead on the moor. "The birds were never weighed, and never carefully examined. Yet without careful weighing and examination it is impossible to come to any reasonable conclusion as to their condition or the cause of death." This has been proved time after time by the committee's field-observer, who has been present when full-feathered, richly-coloured hens, perhaps found almost warm but dead upon their nests, have been weighed in the hand and judged normal, but have been proved to be below normal by the spring balance. In the circumstances, then, the committee seem fully justified in attributing the appearance of "Grouse Disease" to *Trichostrongylus pergracilis*, which they have found to infest the cæca of every acknowledged diseased bird. And while it is possible that the virulent form of disease does sometimes occur, it is also possible that the belief in it is entirely without real reason.

As to the life-history of the strongyle. The worms in the grouse's cæci produce eggs, which pass out of the body with the faeces. If the conditions be moist and from cool to warm (continued drought and heat sterilise the eggs) the larvæ hatch out. About two days later the larva casts its skin and develops rapidly; and eight days from the time of leaving the grouse it is ready to make its way back into the cæca. This is accomplished by climbing up the heather stalks and getting into the top green shoots, on which the grouse feed. And experiment showed that, within fourteen days of its leaving the cæca as an egg, the strongyle is producing eggs. Since countless numbers of eggs are passed by the infected grouse each day the enormous importance of preventing overcrowding on the moor will readily be seen. Still more evident is this in view of the fact that all grouse are infected more or less.

How to diminish the tendency to "pack," by careful management of the heather-burning, and in other ways, is well shown in Lord Lovat's chapter on Moor Management. The maintenance of a plentiful supply of good feed, by systematic heather-burning, draining of bogs, and provision of suitable grit, should promote the health of the birds to such an extent that in the spring, the birds' critical time, they will be able to withstand the attack of the parasite.—*Westminster Gazette*.

B. Coli as a Parasite of Plants

In *Phytopathology* for June J. R. Johnston raises the question of the possibility of *Bacillus coli* being a plant parasite. This organism and its numerous varieties are very widely distributed in nature, but they are known only as harmless saprophytes and no disease in plants has ever been ascribed to them. The experiments carried out by Johnston, however, show that under suitable conditions these organisms may cause considerable damage. Inoculations of a culture of *B. coli* of animal origin were made into the heart wood of cocoanut seedlings. In the course of a month or two in most cases a condition of soft rot appeared around the site of inoculation and from the lesion *B. coli* was recovered. These experiments suggest that certain conditions of rot in plants may be due to bacterial organisms and the supposition is supported by some observations made upon the naturally occurring Budrot disease of cocoanut trees in Cuba. Cultures from diseased trees were inoculated into healthy ones and reproduced the disease. Further reinoculation continued to produce the disease. On study of the organisms in these cultures a considerable number were found to be *B. coli* indistinguishable from strains of animal origin. Johnston accordingly comes to the conclusion that some variety of *B. coli* is the actual cause of Budrot disease in cocoanut trees.—*B. M. J.*

Quarantined Dogs at Southampton—Important Test Case.

An unusual case concerning quarantined dogs was heard at the Southampton County Bench on Friday, October 6, before Admiral C. J. Rowley, in the chair; Mr. R. A. Bayford, K.C.; Mr. H. Milner-White, LL.D.; Col. W. S. Sinkins, and Sir Alfred Swaine-Lethbridge, magistrates.

Mr. William Augustus DellaGana, F.R.C.V.S., Above Bar, Southampton, for whom Mr. G. Thatcher, London, appeared, was summoned for having 37 dogs at the Bitterne Manor Farm Kennels on August 30th last, without having in force such licenses as were required by the Statute.

Mr. F. V. Barber, Deputy Clerk to the Hants County Council, appeared in support of the information on behalf of Supt. Littlewood, and having cited the Act said the point on which the case turned was whether the defendant kept the dogs or not. He had stated that the dogs were imported into Great Britain under the Importation of Dogs Order, 1901, which was made for the purpose of stamping-out rabies. Mr. Barber contended that the defendant so long as he had control of the dogs was liable for the licenses, and the dogs were under his control for six months. No owner outside the United Kingdom could be summoned. Correspondence had passed between the defendant and the County Council, and the defendant said he was exempt from licenses, as he had charge of the dogs for the Board of Agriculture and Fisheries, but Mr. Barber contended that the Importation Order did not affect the general provision of the Act. A letter was sent from the County Council to the defendant stating that although he was

liable for payment, the Council would not enforce payment, provided he produced licenses taken out in the names of the owners of the dogs.

Supt. Littlewood gave evidence as to the number of dogs on the premises, and said no licenses had been taken out. There had been considerable correspondence over the matter, and defendant was still in correspondence with the Board of Agriculture. Some of the animals were sporting dogs, and all were isolated.

Mr. Thatcher, for the defence, urged that the word "keep" in the Act did not mean "keep in custody," but that they were kept for use, and that could not be said to apply to this case. The dogs were in the defendant's control and custody, but only as a place of detention for the Board of Agriculture.

The defendant gave evidence, in the course of which he said he was authorised to keep the dogs. There was no formal license, but an official form was issued, showing the place where the dogs could be kept. This form was issued by the Board of Agriculture, and he had been supplied with one. The dogs were isolated, being kept in separate cages, and were not taken out during the whole period they were there. His impression was that the dogs were being kept by the Government, which had power to have the dogs removed if they wished to do so. The Board provided that the dogs must be kept under control. The dogs were kept at the expense of the owners in accordance with the Order, and could be removed on any occasion when any dangerous disease, such as rabies, broke out. A most important point he wished to remark was that the Government only had power to release the dogs and no one else.

The Bench retired to consider their decision, and returned after an absence of a little over ten minutes,

when the Chairman announced that there was a considerable difference of opinion on the Bench, and they thought it advisable that a case should be taken, to have a judicial opinion as to the real meaning of the word "keep" in the section.

Mr. Barber pressed for a decision.

The Chairman said the majority of the Bench were of opinion that the defendant was clearly responsible, and they imposed a fine of 1s. and costs, allowing two guineas for the complainant's legal expenses.—*The Southern Daily Echo*.

Foot-and-Mouth Disease—The Outbreak near Bridgwater.

The existence of foot-and-mouth in the district was first detected on Thursday, September 28th, amongst a number of dairy cattle on Manor Farm, Blindman's Gate, Middlezoy, near Bridgwater, occupied by Mr. Edward Rawle. Mr. Rawle on Wednesday, September 27th, saw that his cattle were ailing, and consulted Mr. E. W. Bovett, M.R.C.V.S., of Bridgwater, who, on Thursday morning, visited the farm, and on examining the cattle formed the opinion that sixteen of the eighteen cows were suffering from foot-and-mouth disease. Supt. W. H. Williams, of the Bridgwater County Police, wired the fact of the discovery to the Board of Agriculture and Fisheries, and by Thursday night Mr. Jackson, one of the Board's veterinary surgeons, arrived in Bridgwater, and early on Friday morning confirmed Mr. Bovett's opinion. Mr. Stockman, the Board's chief veterinary inspector, arrived during Friday afternoon. He corroborated the opinion of the other veterinaries, Mr. Bovett being complimented on detecting the presence of the disease and the promptness with which he had dealt with the matter. Other officials arrived later, including Sir Edward Clarke, Assistant Permanent Secretary to the Board of Agriculture, and Mr. Smart, Mr. Wrightson, Mr. Munro, and Mr. Mitton, and a scheme of stringent precautions was decided upon. On Saturday Taunton market was closed, and the markets at Bridgwater, Highbridge, Langport, Williton, and Yeovil are similarly affected.

Entrance to the field in which the work of slaughter and cremation was proceeding was strictly forbidden. A police officer was stationed at the gate entrance to the field night and day, and only those officially sanctioned were permitted to enter. Those engaged in the work observed most rigid precautions. To prevent the possibility of carrying the infection to other fields and places no one was allowed to pass out of the field in question without rinsing their hands in disinfectants and dipping their boots in carbolic. The wheels of carts and the hoofs of horses were disinfected, whilst even the roads in the vicinity were disinfected and limed. It is nearly forty years ago that an outbreak of the disease occurred in the Bridgwater district. Old farmers recall that in their early days the disease often ravaged whole herds of cattle in the country, causing enormous loss to agriculturists, but so severe are the precautions taken to-day that the outbreak is usually restricted to a limited area.

The district declared is a very large one, comprising the Bridgwater, Wells, Somerton, Yeovil, Crewkerne, Ilminster, Taunton, and Bishop's Lydeard Petty Sessional Divisions (with some slight exceptions), also parts of the Petty Sessional Divisions of Axbridge, Shepton Mallett, Wincanton, and Wellington, together with all the boroughs in the county, with the exception of Bath.

Speaking at a Liberal meeting at Yeovil on Saturday, Sir Edward Strachey appealed to agriculturists in the infected area and in the county generally to support the Board of Agriculture in the stringent measures they were taking to stamp out the terrible disease. He should

be glad to be able to say, both as the Parliamentary Secretary to the Board of Agriculture and as a Somerset man, that the men of Somerset were loyal to the Board in that matter. (Cheers.)

The following cattle have been destroyed:—On Mr. Rawle's farm—Cattle, 77; pigs, 29. On Mr. Sharman's farm—Cattle, 12; pigs, 2. Total, 120.
